NOTE: Projections of change in real gross domestic product (GDP) and projections for both measures of inflation are percent changes from the fourth quarter of the previous year to the fourth quarter of the year indicated. PCE inflation and core PCE inflation are the percentage rates of change in, respectively, the price index for personal consumption expenditures (PCE) and the price index for PCE excluding food and energy. Projections for the unemployment rate are for the average civilian unemployment rate in the fourth quarter of the year indicated. Each participant's projections are based on his or her assessment of appropriate monetary policy. Longer-run projections represent each participant's assessment of the rate to which each variable would be expected to converge under appropriate monetary policy and in the absence of further shocks to the economy. The projections for the federal funds rate are the value of the midpoint of the projected appropriate target range for the federal funds rate or the projected appropriate target level for the federal funds rate at the end of the specified calendar year or over the longer run. The December projections were made in conjunction with the meeting of the Federal Open Market Committee on December 10–11, 2019. One participant did not submit longer-run projections for the change in real GDP, the unemployment rate, or the federal funds rate in conjunction with the December 10–11, 2019, meeting, and one participant did not submit such projections in conjunction with the June 9–10, 2020, meeting. No projections were submitted in conjunction with the March 2020 FOMC meeting.

1. For each period, the median is the middle projection when the projections are arranged from lowest to highest. When the number of projections is even, the median is the average of the two middle projections.

2. The central tendency excludes the three highest and three lowest projections for each variable in each year.

3. The range for a variable in a given year includes all participants' projections, from lowest to highest, for that variable in that year.

4. Longer-run projections for core PCE inflation are not collected.

Notes: Moody's® Long-Term Corporate Bond Yield Averages have been published daily since 1929. They are derived from pricing data on a regularly-replenished population of over 100 seasoned corporate bonds in the US market, each with current outstandings over $100 million. The bonds have maturities as close as possible to 30 years, with an average maturity of 28 years. They are dropped from the list if their remaining life falls below 20 years or if their ratings change. Bonds with deep discounts or steep premiums to par are generally excluded. All yields are yield-to-maturity calculated on a semi-annual compounding basis. Each observation is an unweighted average, with Average Corporate Yields representing the unweighted average of the corresponding Average Industrial and Average Public Utility observations. Because of the dearth of **Aaa** -rated railroad term bond issues, Moody's® **Aaa** railroad bond yield average was discontinued as of December 18, 1967. Moody's® **Aaa** public utility average was suspended from Jan. 1984 thru Sept. 1984. Oct. 1984 figure for last 14 business days only. The Railroad Bond Averages were discontinued as of July 17, 1989 because of insufficient frequently tradable bonds. The July figures were based on 8 business days.
Because of the dearth of Aaa rated public utility bond issues, Moody's® Aaa public utility bond yield average was discontinued as of December 10, 2001.

SOUTHWESTERN ELECTRIC POWER COMPANY'S RESPONSE TO COMMISSION STAFF'S SIXTH REQUEST FOR INFORMATION

Question No. Staff 6-12:

Refer to the MS Excel file named "SWEPCO 03-31-2020 WCOC," specifically the tab named "LTD." Please confirm that the Series I Hedge Loss (referred to in Cell No. G96) will be fully amortized on January 31, 2022. If not confirmed, please explain in detail.

Response No. Staff 6-12:

Confirmed.

SOUTHWESTERN ELECTRIC POWER COMPANY'S RESPONSE TO COMMISSION STAFF'S SIXTH REQUEST FOR INFORMATION

Question No. Staff 6-14:

Refer to Staff 6-12. Please confirm that, if SWEPCO had not included the Series I Hedge Loss from February 2012 in its calculation, SWEPCO's requested cost of debt would have been 4.08%. If anything other than confirm, please provide calculations and a detailed explanation.

Response No. Staff 6-14:

Confirmed, 4.08%.

A Note on the Relationship Between Firm Size and Return in the Electric Utility Industry

WALLACE DAVIDSON, III*
KENNETH FERRIS**
WILLIAM REICHENSTEIN***

Prior research has argued that given the well-documented inverse relationship between firm size and market returns, smaller utilities should be allowed to earn higher accounting rates of return than larger utilities. To test the validity of this argument, this study investigated the relationship between firm size and market returns in the electric utility industry for the period 1962 through 1985 and found no evidence of either a positive or negative size effect. Moreover, although market returns on utility stocks were found to be higher in January than in non-January months, this January effect was found to be unrelated to firm size. In short, this study found no evidence that allowable accounting rates of return should be adjusted by regulatory authorities to reflect a firm's size.

1. Introduction

The accounting rate of return (ARR) earned by firms operating in a regulated environment is generally established by regulatory authorities on the basis of measures produced under regulatory accounting principles. In some cases, the allowable ARR is based on the level of invested assets (e.g., ROA or ROE), whereas in others it is set as a percentage of costs incurred (e.g., cost plus X percent). In all cases, however, the allowable ARR is relatively unaffected by the size of the regulated firm in that standardized indices are used.[1]

This paper has benefited from the constructive comments of an anonymous reviewer. All errors remain the responsibility of the authors.

1. Size arguments are frequently made in the context of rate determination hearings; hence, although size may be implicitly considered by regulatory authorities in establishing the allowable rate base, it is normally not an explicit consideration in the rate determination process.

0000479

Bolton and Besley [6] argue, however, that given the consistent higher market returns earned by small firms' stocks, a utility's cost of capital and therefore its allowable ARR should reflect its size. That is, smaller utilities should be allowed to earn a higher ARR than larger utilities.

Although there is substantial empirical support for the existence of a size effect [1,2,3,8,9,11,14,16,20,21,25, among others],[2] the presence of this stock market anomaly is not well documented in the utility industry, and what evidence there is suggests that there may be a *large* firm utility effect. Moreover, Schwert [24] questions the appropriateness of adjusting a firm's cost of capital, and by extension the allowable ARR, for the size effect.

Thus, this paper investigates the long-run relationship between firm size and market return for electric utility stocks. If regulatory authorities are to consider the adjustment of allowable ARR by firm size, then the existence of a size effect in the utility industry must first be clearly demonstrated.

2. Investigation

For purposes of this study, we assume the capital markets to be informationally efficient in a semistrong form. Thus, in spite of the presence of artificially controlled ARRs, risk and market return differentials may emerge in response to perceived variability in earnings and cash flows associated with firm size [7,11,12,22,23].

Prior research involving utilities has observed a *positive* relation between a utility's size and market return. For the period 1967–1972, Melicher [18] found a positive relationship between ex post beta and the log of total assets. Similarly, Reichenstein and Davidson [19] observed a significant positive relation between the market value of utilities' common stock and ex ante measures of stock price premiums for the period 1986–1987. Thus, contrary to the findings of the industrial-based size literature, available evidence involving utilities suggests the presence of a positive size effect.

2.1 Sample

The sample for the current study consists of all electric utilities listed on the Center for Research in Security Prices (daily) tapes for pairs of consecutive years, with not more than 10 days of missing data in either year. The only firms eliminated by this restriction are those whose stock was delisted during a two-year period. The study period is 1962 through

2. Recent evidence [12,13] suggests that the size effect may be smaller than previously thought.

Downloaded from jaf.sagepub.com by guest on September 6, 2012

1985; however, because one additional year is needed to generate market model parameters, results are reported for only 1963–1985. The sample varies by year from 90 to 103 firms.

2.2 Analysis

At the end of each year ($t - 1$), the market value of equity for each firm was computed and then used to assign the firm to one of four portfolios based on a ranking of relative market value. Firms assigned to MV_1 represent the lowest quartile of relative market value for a given year, whereas those assigned to MV_4 represent the highest quartile of relative market value. Using parameter estimates obtained for year $t - 1$, daily abnormal returns were computed for year t. These returns were then summed for each company to yield a cumulative abnormal return (CAR_t), and grouped by firm size to produce a portfolio CAR. Cumulative abnormal returns for each of the four equally weighted portfolios were calculated using two separate return-generating models. The first model was the market model, with parameter estimates for year $t - 1$ obtained by regressing daily returns against the returns on the value-weighted market index. The second model was the aggregate beta model proposed by Dimson [13] to minimize measurement problems associated with infrequently traded stocks. The results for the aggregate beta model are not specifically discussed here in that it yielded qualitatively similar results and supported similar conclusions to those of the market model.[3]

3. Empirical Results

3.1 Annual Results

Table 1 summarizes the average annual abnormal returns for the four portfolios generated by the market model. The average CARs do not differ significantly over the investigated period 1963 to 1985 ($F_{3,15} = 0.0394$). The range of values is small (i.e., -0.0474 [MV_3] to -0.0290 [MV_4]), and they neither increase nor decrease monotonically with size. In short, the data provide no evidence of *either* a negative or a positive annual size effect.

Moreover, Table 2 shows the distributions of average raw returns and average betas across the four portfolios. Neither raw returns nor betas

3. The Dimson model [13] is appropriate when stocks trade infrequently, which is primarily a small firm phenomenon. We reach the same conclusions with the market model and the Dimson aggregate beta model. The results for the aggregate beta model are presented in Table 1, but are not discussed.

Downloaded from jaf sagepub com by guest on September 6, 2012

TABLE 1

Tests for an Annual Firm Size Effect

Average Annual Abnormal Returns	MV_1	MV_2	MV_3	MV_4
Market Model $F_{3,15} = 0.0394$	−0.0313	−0.0343	−0.0474	−0.0290
Aggregate Beta Model $F_{3,15} = 0.0700$	0.0458	0.0449	0.0383	0.0301

vary systematically with firm size, which implies that there are no risk differences between small and large utilities.

3.2 January Effect

A January effect is closely associated with the size effect [4,26]. It appears in two distinct ways. First, average returns for all size categories are larger in January than in non-January months (referred to as the "seasonal returns effect"). And second, the difference between annual returns on smaller and larger firms is concentrated in January (referred to as the "January small firm effect").

The seasonal returns effect is a stock market anomaly, possibly indicating that stocks in general represent a riskier investment in January than in other months. The existence of such an effect among utility stocks neither suggests nor justifies an adjustment to a firm's cost of capital or allowable ARR. A January small firm effect, on the other hand, would suggest that the riskiness of stocks varies systematically with firm size, and thus if present, might imply that allowable ARRs should be adjusted to reflect firm size.

Table 3 summarizes the tests for a seasonal returns effect. The tests are based on abnormal returns cumulated monthly for each of the four portfolios and for the aggregate portfolio of all utility stocks. The monthly returns permit tests of significant difference between the abnormal returns in January

TABLE 2

Average Beta and Raw Returns by Portfolio

	MV_1	MV_2	MV_3	MV_4
Average Beta $F_{3,15} = 1.171$	.481	.532	.522	.539
Average Raw Return $F_{3,15} = 0.890$	.078	.079	.065	.084

Note: In the mean column, the F statistic from a general linear model appears in parentheses below the mean. In the column labeled "Other Tests," significance is indicated by T, D, and/or S if the month's abnormal return is significantly different from January's according to Tukey's, Dunn's, and/or Scheffe's tests, respectively. Significance for the F test is noted with a ** or * for significance at the 0.01 and 0.05 levels, respectively.

TABLE 4

Summary of Tests for a January Firm Size Effect

Market Model	MV_1	MV_2	MV_3	MV_4
Average January Abnormal Return $F_{3,15} = 0.349$	0.0164	0.0232	0.0186	0.0109

and in the other individual months (rows 1 through 11), and between the abnormal returns in January and the other months in aggregate (row 12). The statistical significance of the differences was evaluated using an F statistic from a general linear model and with the Tukey, Dunn, and Scheffe tests; significant differences at the .05 level for these tests are labeled T, D, or S, respectively.

The results in Table 3 indicate that (1) the abnormal returns in January were significantly higher than the average of the non-January months for all four size portfolios and for the aggregate sample; (2) the abnormal returns in January were significantly higher than the returns for the other months in 8 of the 11 tests for the aggregate sample; and (3) for the four portfolios, the abnormal returns in January were significantly greater than the returns in individual months in 17 of the 44 comparisons. Thus, the data provide some evidence of a seasonal returns effect.[4]

Table 4 compares the January returns for MV_1 through MV_4 to investigate for the presence of a January small firm effect for the sample of utilities. The F statistic comparing the mean returns was 0.349 and is statistically insignificant. Even the nominal size of the returns indicates the absence of a relationship with firm size.

3.3 Analysis of Results

One explanation for the positive association between beta and firm size observed by Melicher [18] and between ex ante risk premium and size observed by Reichenstein and Davidson [19] may involve the time periods investigated.[5] Both studies examined periods when large firms generally

4. One possible explanation for the seasonal returns effect is that more information becomes available in January than in other months because of the number of companies with December 31 year-end dates. The release (or leak) of year-end information may produce a significant reduction in uncertainty, lowering of risk, and raising of stock prices across the range of firm size [1]. If the seasonal returns effect represents a predictable pattern, presumably the natural workings of self-interested investors should have eliminated it.

5. Melicher [18] used data for the period 1967 to 1971. For this same time period, the average CAR for MV_1 through MV_4 for the current sample of utilities was −.0569, −.0824, −.0783, and −.0682, respectively. The F-statistic for these values is insignificant, suggesting that an explanation based on time period differences can be rejected.

Downloaded from jaf sagepub com by guest on September 6 2012

outperformed small firms. Brown, Kleidon, and Marsh [8] report that the size effect is unstable over time; thus, it is possible that the direction and strength of the size effect may vary as a function of the time period investigated. Nonetheless, over the 23-year period investigated in this study, no evidence of a material size effect was observed.

Research since Melicher also suggests that his results may have been influenced by error-in-variables or estimation problems. The error-in-variables problems include questions involving the reliability of individual betas (see [5], and [23], among others), and the use of the log of total assets as a measure of size. Brown, Kleidon, and Marsh, for instance, indicate that the size effect is best measured by the log of market value of common equity. Moreover, the presence of heteroskedasticity in the cross-sectional sample—a possibility apparently not considered in earlier research—may produce biased t statistics.

Further, the size difference between the companies in our sample may not be as large as the size difference in other studies. The equity value of the largest firms in 1985 (valued as of 31 December 1984) was $6.5 billion and in 1963 was $72.5 million. Comparable figures for the smallest firms are $40.2 million in 1985 and $5.7 million in 1963.[6] Even this range, however, should permit detection of a significant size effect if it exists, and our results do not reveal even a nominal size effect (ignoring tests of significance).

Finally, recent research [10,11,16] suggests that the small firm effect is related to the losing firm effect: smaller firms on organized exchanges consist largely of firms that have recently lost market value, and because of the leverage effect or increased financial distress, they become risky firms. The relative stability of utility stocks, and the regulatory charge to avoid possible financial distress, suggest that utility companies may be relatively exempt from the losing firm effect.[7]

4. Summary and Implications

Substantial empirical evidence indicates that small firm stocks consistently produce higher risk-adjusted returns than large firm stocks. On the

6. Basu [3] reports the median for his small firm portfolio to be $30.3 million over the period 1963 to 1979. Our small firm portfolio of utilities had a median of $49.8 million over this same time period. Hence, the utilities in our sample are not as small as the firms in Basu's small firm portfolio, but they are smaller than his second-ranked group, which had a median of $81.6 million. We believe there are sufficiently large size differences among the utilities in our sample to permit a valid test of the size effect.

7. We define a "losing firm" as one whose stock experienced negative returns in a given year. For most utilities, the largest component of return is dividend yield, so stock price decreases generally do not cause annual negative returns. For our sample, drawn from 1963 through 1985, the proportion of losing stocks in MV_1 through MV_4 was 22, 17, 22, and 24 percent, respectively. We conclude that small utility stocks are not dominated by losing stocks.

Downloaded from jaf sagepub com by guest on September 6, 2012

basis of this evidence, some researchers have argued that a utility's cost of capital and therefore its allowable ARR should be adjusted to reflect a firm's size.

Although the extant literature provides evidence of two within-industry studies indicating that the relation between utility size and returns is positive, we arrive at a different conclusion. On the basis of historical returns on electric utility stocks for the period 1963 through 1985, we are unable to reject the null hypothesis that annual and January-only abnormal returns are equal among utility portfolios of varying size. Further, raw returns and betas were not found to vary systematically with portfolio size.

The evidence obtained in this study indicates that abnormal returns in January exceed the average abnormal returns in the other eleven months. However, this seasonal returns effect was found to exist across *all* size portfolios, and hence we conclude that it is unrelated to firm size. Thus, our results suggest that neither large nor small utilities merit a premium because of their size.

The implications of our findings for regulatory officials and for regulatory accounting standard-setters are straightforward: we find no evidence among the electric utility industry during the period 1963 to 1985 to suggest that a utility's cost of capital or its allowable ARR should be adjusted to reflect firm size.

UTILITY STOCKS AND THE SIZE EFFECT: AN EMPIRICAL ANALYSIS

Annie Wong*

I. Introduction

The objective of this study is to examine whether the firm size effect exists in the public utility industry. Public utilities are regulated by federal, municipal, and state authorities. Every state has a public service commission with board and varying powers. Often their task is to estimate a fair rate of return to a utility's stockholders in order to determine the rates charged by the utility. The legal principles underlying rate regulation are that "the return to the equity owner should be commensurate with returns on investments in other enterprises having corresponding risks," and that the return to a utility should be sufficient to "attract capital and maintain credit worthiness." However, difficulties arise from the ambiguous interpretation of the legal definition of *fair and reasonable rate of return* to an equity owner.

Some finance researchers have suggested that the Capital Asset Pricing Model (CAPM) should be used in rate regulation because the CAPM beta can serve as a risk measure, thus making risk comparisons possible. This approach is consistent with the spirit of a Supreme Court ruling that equity owners sharing similar level of risk should be compensated by similar rate of return.

The empirical studies of Banz (1981) and Reinganum (1981) showed that small firms tend to earn higher returns than large firms after adjusting for beta. This phenomenon leads to the proposition that firm size is a proxy for omitted risk factors in determining stock returns. Barry and Brown (1984) and Brauer (1986) suggested that the omitted risk factor could be the differential information environment between small and large firms. Their argument is based on the fact that investors often have less publicly available information to assess the future cash flows of small firms than that of large firms. Therefore, an additional risk premium should be included to determine the appropriate rate of return to shareholders of small firms.

The samples used in prior studies are dominated by industrial firms, no one has examined the size effect in public utilities. The objective of this study is to extend the empirical findings of the existing studies by investigating whether the size effect is also present in the utility industry. The findings of this study have important implications for investors, public utility firms, and state regulatory agencies. If the size effect does exist in the utility industry, this would suggest that the size factor should be considered when the CAPM is being used to determine the fair rate of return for public utilities in regulatory proceedings.

II. Information Environment of Public Utilities

In general, utilities differ from industrialcs in that utilities are heavily regulated and they follow similar accounting procedures. A public utility's financial reporting is mainly regulated by the Securities and Exchange Commission (SEC) and the Federal Energy Regulatory Commission (FERC). Under the Public Utility Holding Company Act of 1935, the SEC is empowered to regulate the holding company systems of electric and gas utilities. The Act requires registration of public utility holding companies with the SEC. Only under strict conditions would the purchase, sale or issuance of securities by these holding companies be permitted. The purpose of the Act is to keep the SEC and investors informed of the financial conditions of these firms. Moreover, the FERC is in charge of the interstate operations of electric and gas companies. It requires utilities to follow the accounting procedures set forth in its Uniform Systems of Accounts. In particular, electric and gas utilities must request their Certified Public Accountants to certify that certain schedules in the financial reports are in conformity with the Commission's accounting requirements. These detailed reports are submitted annually and are open to the public.

*Western Connecticut State University. The author thanks Philip Perry, Robert Hagerman, Eric Press, the anonymous referee, and Clay Singleton for their helpful comments.

0000489

The FERC requires public utilities to keep accurate records of revenues, operating costs, depreciation expenses, and investment in plant and equipment. Specific financial accounting standards for these purposes are also issued by the Financial Accounting Standards Board (FASB). Uniformity is required so that utilities are not subject to different accounting regulations in each of the states in which they operate. The ultimate objective is to achieve comparability in financial reporting so that factual matters are not hidden from the public view by accounting flexibility.

Other regulatory reports tend to provide additional financial information about utilities. For example, utilities are required to file the FERC Form No. 1 with the state commission. This form is designed for state commissions to collect financial and operational information about utilities, and serves as a source for statistical reports published by state commissions.

Unlike industrials, a utility's earnings are predetermined to a certain extent. Before allowed earnings requests are approved, a utility's performance is analyzed in depth by the state commission, interest groups, and other witnesses. This process leads to the disclosure of substantial amount of information.

III. Hypothesis and Objective

Due to the Act of 1935, the Uniform Systems of Accounts, the uniform disclosure requirements, and the predetermined earnings, all utilities are reasonably homogeneous with respect to the information available to the public. Barry and Brown (1984) and Brauer (1986) suggested that the difference of risk-adjusted returns between small and large firms is due to their differential information environment. Assuming that the differential information hypothesis is true, then uniformity of information availability among utility firms would suggest that the size effect should not be observed in the public utility industry. The objective of this paper is to provide a test of the size effect in public utilities.

IV. Methodology

1. Sample and Data

To test for the size effect, a sample of public utilities and a sample of industrials matched by equity value are formed so that their results can be compared. Companies in both samples are listed on the Center for Research in Security Prices (CRSP) Daily and Monthly Returns files. The utility sample includes 152 electric and gas companies. For each utility in the sample, two industrial firms with similar firm size (one is slightly larger and the other is slightly smaller than the utility) are selected. Thus, the industrial sample includes 304 non-regulated firms.

The size variable is defined as the natural logarithm of market value of equity at the beginning of each year. Both the equally-weighted and value-weighted CRSP indices are employed as proxies for the market returns. Daily, weekly and monthly returns are used. The Fama-MacBeth (1973) procedure is utilized to examine the relation between risk-adjusted returns and firm size.

2. Research Design

All utilities in the sample are ranked according to the equity size at the beginning of the year, and the distribution is broken down into deciles. Decile one contains the stocks with the lowest market values while decile ten contains those with the highest market values. These portfolios are denoted by MV_1, MV_2, ..., and MV_{10}, respectively.

The combinations of the ten portfolios are updated annually. In the year after a portfolio is formed, equally-weighted portfolio returns are computed by combining the returns of the component stocks within the portfolio. The betas for each portfolio at year t, β_p's, are estimated by regressing the previous five years of portfolio returns on market returns:

$$\tilde{R}_{pt} = \alpha_p + \hat{\beta}_p \tilde{R}_{mt} + \tilde{U}_{pt} \qquad (1)$$

where

R_{pt} = periodic return in year t on portfolio p

R_{mt} = periodic market return in year t

U_{pt} = disturbance term.

Banz (1981) applied both the ordinary and generalized least squares regressions to estimate β; and concluded that the results are essentially identical (p.8). Since adjusting for heteroscedasticity does not necessarily lead to more efficient estimators, the ordinary least squares procedures are used in this study to estimate β in equation (1).

The following cross-sectional regression is then run for the portfolios to estimate γ_i, i = 0, 1, and 2:

$$R_{pt} = \gamma_0 + \gamma_1 \hat{\beta}_{pt} + \gamma_2 \hat{S}_{pt} + U_{pt} \qquad (2)$$

where

$\hat{\beta}_{pt}$ = estimated beta for portfolio p at year t, t=1968, ..., 1987

$\hat{S}_{pt}$ = mean of the logarithm of firm size in portfolio p at the beginning of year t

U_{pt} = disturbance term.

Depending on whether daily, weekly or monthly returns are used, a portfolio's average return changes periodically while its beta and size only change once a year. The γ_1 and γ_2 coefficients are estimated over the following four subperiods: 1968-72, 1973-77, 1978-82 and 1983-1987. If portfolio betas can fully account for the differences in returns, one would expect the average coefficient for the beta variable to be positive and for the size variable to be zero. A t-statistic will be used to test the hypothesis. The coefficients of a matched sample are also examined so that the results between industrial and utility firms can be compared.

V. Analysis of Results

1. Equity Value of the Utility Portfolios

The mean equity values of the ten size-based utility portfolios are reported in Table 1. Panels A and B present the average firm size of these portfolios at the beginning and end of the test period, 1968-1987. The first interesting observation from Table 1 is that the difference in magnitude between the smallest and the largest market value utility portfolios is tremendous. In Panel A, the average size of MV_1 is about $31 million while that of MV_{10} is over $1.4 billion. In Panel B, that is twenty years later, they are $62 million and $5.2 billion, respectively. Another interesting finding is that there is a substantial increase in average firm size from MV_8 to MV_{10}. Since these two findings are consistent over the entire test period, the average portfolio market values for interim years are not reported. These results are similar to the empirical evidence provided by Reinganum (1981).

The utility sample in this study contains 152 firms whereas Reinganum's sample contains 535 firms that are mainly industrial companies. Two conclusions may be drawn from the results of the Reinganum study and this one. First, utilities and industrials are similar in the sense that their market values vary over a wide spectrum. Second, the fact that there is a huge jump in firm size from MV_9 to MV_{10} indicates that the distribution of firm size is positively skewed. To correct for the skewness problem, the natural logarithm of the mean equity value of each portfolio is calculated. This variable is then used in later regressions instead of the actual mean equity value.

2. Betas of the Utility and Industrial Samples

The betas based on monthly, weekly and daily returns are reported for the utility and industrial samples. For simplicity, they will be referred to as monthly, weekly, and daily betas. In all cases, five years of returns are used to estimate the systematic risk. The betas estimated over the 1963-67 time period are used to proxy for the betas in 1968, which is the beginning of the test period. By the same token, the betas obtained from the time period 1982-86 are used as proxies for the betas in 1987, which is the end of the test period.

The betas from using the equally-weighted and value-weighted indices are calculated in order to check whether the results are affected by the choice of market index. Since the results are similar, only those obtained from the equally-weighted index are reported and analyzed.

Table 2 reports the monthly, weekly and daily betas of the two samples at the beginning and end of the test period. Panel A shows the various betas of the industrial portfolios. Two conclusions may be drawn. First, in the 1960's, smaller market value portfolios tend to have relatively larger betas. This is consistent with the empirical findings by Banz (1981) and Reinganum (1981). Second, this trend seems to vanish in the 1980's, especially when weekly and daily returns are used.

The betas of the utility portfolios are presented in Panel B. The table shows that none of the utility betas are greater than 0.71. A comparison between Panels A and B reveals that utility portfolios are relatively less risky than industrial portfolios after controlling for firm size. The comparison also reveals that, unlike industrial stocks, betas of the utility portfolios are not related to the market values of equity.

The negative correlation between firm size and beta in the industrial sample may introduce a multicolinearity problem in estimating equation (2). Banz (p.11) had addressed this issue and concluded that the test results are not sensitive to the

multicolinearity problem. For the utility sample, this problem does not exist.

3. Tests on the Coefficients of Beta and Size

The beta and firm size are used to estimate γ_1 and γ_2 in equation (2). A t-statistic is used to test if the mean values of the gammas are significantly different from zero. The tests were performed for four 5-year periods which are reported in Table 3. The mean of the gammas and their t-statistic are presented in Panel A for the utilities and in Panel B for the industrial firms.

The empirical results for the utility sample are reported in Panel A of Table 3. When monthly returns are used, 60 regressions were run to obtain 60 pairs of gammas for each of the 5-year periods. When daily returns are used, over 1200 regressions were run for each period to obtain the gammas. The results are similar: in all of the time periods tested, none of the average coefficients for beta and size are significantly different from zero. When weekly returns are used, 260 pairs of gammas were obtained. The average coefficients for beta are not significant in any test period, and the average coefficients for size are not significant in three of the test periods. For the test period of 1978-82, the average coefficient for size is significantly negative at a 5% level.

The test results for the industrial sample are reported in Panel B of Table 3. When monthly returns are used, the average coefficient estimates for size and beta are significant and have the expected sign only in the 1983-87 test period. When weekly returns are used, only the size variable is significantly negative in the 1978-82 period. When daily returns are used, the coefficient estimates for betas and size are not significant at any conventional level.

According to the CAPM, beta is the sole determinant of stock returns. It is expected that the coefficient for beta is significantly positive. However, the empirical findings reported in this study and in Fama and French (1992) only provide weak support for beta in explaining stock returns. The empirical findings in this study also suggest that the size effect varies over time. It is not unusual to document the firm size effect at certain time periods but not at others. Banz (1981) found that the size effect is not stable over time with substantial differences in the magnitude of the coefficient of the size factor (p.9, Table 1). Brown, Kleidon and Marsh (1983) not only have shown that size effect is not constant over time but also have reported a reversal of the size anomaly for certain years.

The research design of this study allows us to keep the sample, test period, and methodology the same with the holding-period being the only variable. The size effect is documented for the industrial sample in one of the four test periods when monthly returns are used and in another when weekly returns are used. When daily returns are used, no size effect is observed. For the utility sample, the size effect is significant in only one test period when weekly returns are used. When monthly and daily returns are used, no size effect is found. Therefore, this study concludes that the size effect is not only time-period specific but also holding-period specific.

VI. Concluding Remarks

The fact that the two samples show different, though weak, results indicates that utility and industrial stocks do not share the same characteristics. First, given firm size, utility stocks are consistently less risky than industrial stocks. Second, industrial betas tend to decrease with firm size but utility betas do not. These findings may be attributed to the fact that all public utilities operate in an environment with regional monopolistic power and regulated financial structure. As a result, the business and financial risks are very similar among the utilities regardless of their sizes. Therefore, utility betas would not necessarily be expected to be related to firm size.

The objective of this study is to examine if the size effect exists in the utility industry. After controlling for equity values, there is some weak evidence that firm size is a missing factor from the CAPM for the industrial but not for the utility stocks. This implies that although the size phenomenon has been strongly documented for the industrialcs, the findings suggest that there is no need to adjust for the firm size in utility rate regulations.
