### Q. HOW WAS YOUR TARGET RESERVE OF \$6.55 MILLION DEVELOPED?

A. As indicated above, I ran a Monte Carlo simulation on the loss history of
CenterPoint Houston. From the 5,000 iterations of simulated experience, I was able
to determine that in any 25-year period, the largest annual expected impact on the
self-insurance reserve is approximately \$6.55 million.

#### 7 Q. WHY IS THIS RESERVE LEVEL APPROPRIATE?

8 A. This reserve level is the amount that should be carried by CenterPoint Houston to 9 make an actuarially sound provision for coverage of the self-insured losses. The 10 target reserve will be sufficient if annual losses are equal to or less than the target 11 in a given year provided the reserve is already in place at its target amount; but if 12 the actual losses exceed the amount accrued for the expected annual amount for 13 several years in a row, the self-insurance reserve may be depleted.

For example, once the reserve level has been reached, if there are several years with losses of approximately \$4 million, then the reserve balance will remain relatively stable. However, if there are two consecutive years with annual aggregate losses of more than \$8 million each year, the self-insurance reserve would be in a deficit position. The deficit amount would need to be collected from future ratepayers.

1	Q.	DOES THE PRESENCE OF A RESERVE OR ACCRUAL DESIGNED TO
2		REACH A TARGET LEVEL ENSURE THAT THE RESERVE BALANCE
3		WILL BE ADEQUATE TO COVER EVERY PROPERTY LOSS?

A. No. As explained above, once the reserve reaches its targeted level, on average it
should cover typical annual losses, but should also be enough to cover a once in
25-year event. Larger loss events are possible, and should one occur, the reserve
would not cover the full amount. Those events are much less common and
therefore, I recommended that CenterPoint Houston not consider those events in
establishing the target level for the reserve balance.

#### 10 Q. WHAT IS THE BALANCE OF THE RESERVE?

A. As shown on Rate Filing Package Schedule II-B-7, page 1 of 2, the adjusted balance
of the reserve is a deficit balance of approximately (\$5.791 million) as of
December 31, 2018.

# 14 Q. WHAT ARE THE INDIVIDUAL COMPONENTS OF THE ANNUAL 15 ACCRUAL TO THE SELF-INSURANCE RESERVE INDICATED BY 16 YOUR ANALYSIS?

17 A. The annual amount to be accrued each year is \$7.685 million, which is composed 18 of two elements. First, there is \$3.575 million each year to provide for the year's 19 annual expected covered losses from property loss event damages. Second, there 20 should be an accrual of \$4.11 million each year for three years to provide for the 21 variation in annual losses from year to year by building the total self-insurance 22 reserve from the test year balance of approximately (\$5.791 million) up to the \$6.55

million level. I have recommended a three-year period to balance the interests of
 future ratepayers versus past ratepayers.

### 3 Q. ARE THESE CALCULATIONS PREPARED IN ACCORDANCE WITH 4 GENERALLY ACCEPTED ACTUARIAL PROCEDURES?

5 Yes. The process reflects generally accepted actuarial procedures. However, I have A. 6 made certain adjustments to reflect the nature of ratemaking for public utilities. For 7 example, it would be customary to project losses to the anticipated cost level of the 8 future time period during which rates will be in effect. Because of the historical 9 test year approach to utility ratemaking and the adjustment of expense items based 10 on known and measurable quantities only, I have limited loss adjustments to the 11 cost levels. The dates to which the losses were adjusted reflect the dates of the most 12 recent indices available at the time the adjustments were made. On the other hand, 13 common actuarial practice would be to project the cost of expected losses to the 14 future period when they will be incurred, a level that would be greater than the level 15 recommended in my testimony.

In addition, no adjustment has been made to reflect future increased exposure to loss. For example, in 2019 CenterPoint Houston may own more property in the service area that is exposed to loss than it had in years prior to 2018. This would increase the exposure to loss, and lead to a higher recommended reserve.

#### 21 Q. HOW WILL THE SELF-INSURANCE RESERVE ACCRUALS OPERATE?

A. The excess of annual expected losses over actual self-insured losses, to the extent
 there is any such excess, will accrue to the self-insurance target reserve and cause

1		CenterPoint Houston to reach its target earlier, all other things being equal. Any						
2		deficiency between the annual expected losses and the actual self-insured layer						
3		losses in any calendar year will serve to extend the period over which the Company						
4		can expect to reach its target.						
5		VI. <u>COST BENEFIT ANALYSIS</u>						
6	Q.	HOW DID YOU DETERMINE THAT SELF-INSURANCE IS A LOWER						
7		COST ALTERNATIVE FOR THOSE T&D PROPERTY LOSSES						
8		GREATER THAN \$100,000?						
9	A.	There are at least two ways to consider the cost-benefit of self-insuring these losses.						
10		The first is by considering the manner in which insurance companies set premiums						
11		and the second is by an actual comparison of the recommended self-insurance						
12		accrual to the estimated insurance premium for comparable coverage, if available.						
13	Q.	WHAT ASPECTS OF AN INSURANCE COMPANY'S PREMIUM						
14		DETERMINATION PROCESS DID YOU CONSIDER IN CONCLUDING						
15		THAT THE SELF-INSURANCE APPROACH FOR THE DESIGNATED						
16		LAYER OF LOSSES IS APPROPRIATE?						
17	A.	Insurance companies include provisions in their premiums for all costs associated						
18		with the transfer of the insurance risk. Hence, they include provisions for losses,						
19		loss adjustment expenses, non-loss related expenses, premium taxes, and a profit.						
20		A self-insurance reserve, such as CenterPoint Houston's reserve, does not						
21		need to include many of the provisions other than those for losses and loss-related						
22		expenses. For example, a self-insurance reserve does not need to pay premium						
23		taxes and other state-imposed fees. An insurance company needs to make a profit						
24		on the business it transacts. A self-insurance reserve, on the other hand, is not						

1		intended to generate a profit and, hence, no provision for profit needs to be included
2		in the accrual provisions. Insurance companies also incur costs associated with the
3		acquisition of insured risks. The largest of these expenses is that associated with
4		the payment of commissions to insurance agents or brokers to place the business.
5		A self-insurance reserve does not include any provision for commissions because
6		there are no insurance agents or brokers involved. Finally, an insurance company
7		must expend resources to underwrite risks, market its products, and maintain
8		overhead expenses. A self-insurance reserve does not need to provide for these
9		costs.
10		In summary, self-insurance saves the costs of premium taxes, commissions,
11		profit, and many of the general expenses associated with the operation of an
12		insurance company.
13	Q.	WHAT OTHER COST BENEFIT ANALYSIS HAVE YOU RELIED UPON
14		TO SHOW THAT THE COST FOR THE SELF-INSURED LAYER IS
15		LOWER THAN THE COST OF PURCHASING INSURANCE FOR THE
16		SAME LAYER OF INSURANCE AND IS IN THE INTEREST OF THE
17		COMPANY'S CUSTOMERS?
18	A.	Comparing the cost of self-insurance versus the cost of purchasing insurance
19		establishes that it is more cost effective for CenterPoint Houston to self-insure. As
20		discussed in the testimony of Company witness Robert B. McRae, CenterPoint
21		Houston's risk manager has tried to obtain coverage for T&D assets damaged by
22		storms. The risk manager has been unable to find coverage at any cost reasonably

1		close to the cost of self-insurance. This is due to the extensive damage caused by							
2		hurricanes to electric utilities across the country in the past several years.							
3		VII. CONCLUSION							
4	Q.	WHAT DO YOU CONCLUDE REGARDING CENTERPOINT							
5		HOUSTON'S REQUEST FOR SELF-INSURANCE RESERVE TO COVER							
6		T&D PROPERTY LOSSES?							
7	A.	I have conducted an analysis that meets the Commission's rule requirements and							
8		have demonstrated that self-insurance is necessary and desirable given the lack of							
9		reasonably priced commercial insurance. I have determined that a target reserve of							
10		\$6.55 million is reasonable, and the amount is in fact less than the amount							
11		previously approved for CenterPoint Houston by the Commission. I have also							
12		determined that an annual accrual of \$7.685 million, which is comprised of amounts							
13		intended to cover expected property losses and to build up the reserve balance from							
14		its current deficit level to a target balance of \$6.55 million, is reasonable.							
15	Q.	DOES THIS CONCLUDE YOUR DIRECT TESTIMONY?							

16 A. Yes, at this time.

#### **STATE OF TEXAS §** § § COUNTY OF COLLIN

#### **AFFIDAVIT OF GREGORY S. WILSON**

BEFORE ME, the undersigned authority, on this day personally appeared Gregory S. Wilson who having been placed under oath by me did depose as follows:

- 1. "My name is Gregory S. Wilson. I am of sound mind and capable of making this affidavit. The facts stated herein are true and correct based upon my personal knowledge.
- 2. I have prepared the foregoing Direct Testimony and the information contained in this document is true and correct to the best of my knowledge."

Further affiant sayeth not.

Jun Puth Gregory S. Wilson

SUBSCRIBED AND SWORN TO BEFORE ME on this  $\frac{18^{11}}{1000}$  day of March, 2019.

in and for the State of TEXAS

My commission expires: //-26-20

#### GREGORY S. WILSON, FCAS, MAAA Vice President and Principal

#### **CURRENT POSITION**

Mr. Wilson is a Vice President and Principal with Lewis & Ellis, Inc.

#### **EXPERIENCE:**

Mr. Wilson's responsibilities include evaluating the adequacy of insurance company reserve levels in conjunction with actuarial certification for the annual statement as well as state insurance department examinations. He also evaluates the adequacy of loss reserves for several self-insured companies. In addition, he performs rate level analyses for insurance companies and helps them prepare filings for the state insurance departments, as well as self-insured analyses for electric utilities and prepares testimony for the Public Utility Commission.

Prior to joining the firm, Mr. Wilson was a Principal Consultant at PricewaterhouseCoopers LLP. His responsibilities were similar to his current responsibilities. In addition, he reviewed retrospective rating calculations for several companies involved in class action litigation in Texas. He also performed several funding analyses for governmental entities.

Prior to joining PricewaterhouseCoopers LLP, Mr. Wilson was Vice President of Amica Mutual Insurance Company in Providence, Rhode Island.

2907

There, he supervised all aspects of ratemaking, from procedures to recommendations, helped negotiate the purchase of reinsurance, determined IBNR, developed a strategy for Massachusetts Automobile and developed other states' residual market strategies, in particular, New York and New Jersey.

#### **EDUCATION**

Mr. Wilson received his Bachelor's degree in Applied Mathematics from the University of Rhode Island.

#### PROFESSIONAL ACTIVITIES

Mr. Wilson is a former member of the Casualty Actuarial Society's Examination Committee, Committee on Ratemaking, and Committee on Reserving. He is also a Past President of the Southwest Actuarial Forum.

Greg:

Attached is the document which CenterPoint Houston's risk manager obtained, describing the lack of availability of electric transmission and distribution property insurance. Pending further instructions, please treat this information as Confidential.

Thanks.

Robert W. Jackson Manager of Regulatory Affairs | Regulatory Portfolio Management Organization 713.207.5584 w. <u>CenterPointEnergy.com</u>

### MCGRIFF, SEIBELS & WILLIAMS, INC. POWER MARKET UPDATE

INSURANCE BROKERAGE SERVICES

March 5<sup>th</sup>, 2019

.

### **Other Miscellaneous**

#### **Transmission and Distribution Lines**

- · There continues to be no viable market place for meaningful T&D coverage
  - Insurance companies do not have reinsurance to protect them so explicitly exclude the coverage on property policies
  - A few syndicates in London may write small net lines but available capacity is minimal maybe \$20MM \$25MM excess of large retentions
  - No US markets will offer capacity
  - With rare exception insurance market in general consider T&D lines uninsurable
- AEGIS product that was being promoted in 2018 was not successful
  - MSW are aware of no utilities that purchased the product
  - Limited capacity (~\$25MM), extremely high rate on line (15-20%) and large attachment points
  - Not meaningful protection for large highly exposed utility companies
- Parametric Products are available
  - Swiss Re and other Alternative Risk companies
  - Minimum dual trigger products (wind speed thresholds and geographic touch points = varying payout amounts)
  - Similar shortcomings to above (limited capacity and high rate on line type products)
  - East coast example: up to 25% rate on line for \$10MM in occurrence limits
  - Max. payout achieved if wind field measured at specific locations exceed 90 mph
  - Allows for one reinstatement of the limit

1	<b>EXECUTIVE SUMMARY OF J. STUART MCMENAMIN</b>
2	My testimony explains how detailed data from the CenterPoint Energy advanced
3	metering system is used to adjust daily and monthly energy usage and billing determinants
4	in order to ensure that its rates are set on data that reflect normal weather, as contemplated
5	by the Public Utility Commission's rate filing package instructions. The weather
6	adjustment method used is reasonable and necessary when preparing rates. Specifically, I
7	address:
8	<ul> <li>weather adjustment models for daily energy;</li> </ul>
9	<ul> <li>weather adjustment models for class peaks and CP values;</li> </ul>
10	<ul> <li>weather adjustment models for customer demand;</li> </ul>
11	<ul> <li>calculation of normal weather;</li> </ul>
12	<ul> <li>unadjusted test year load data;</li> </ul>
13	<ul> <li>adjusted test year load data; and</li> </ul>
14	<ul> <li>adjusted revenue month customer demand and billing demand.</li> </ul>
15	Utilities make weather adjustments to ensure that rates are set to meet revenue
16	requirements in a year with normal weather. By looking at weather data from recent years,
17	we can construct a test year weather pattern that is representative of typical weather
18	conditions. This insures that rates are not based upon the specific and possibly
19	uncharacteristic weather pattern that occurred in one particular year. The weather
20	adjustment methods summarized in my testimony are consistent with industry practice and
21	the weather adjustment results provide accurate estimates of the impact of weather
22	deviations from normal in 2018. Schedules related to the weather adjustment of energy,
23	class peak, class coincident loads, and customer demand are attached to my testimony.

1		DIRECT TESTIMONY OF J. STUART MCMENAMIN
2		I. INTRODUCTION AND QUALIFICATIONS
3	Q.	PLEASE STATE YOUR NAME, BUSINESS ADDRESS, AND PLACE OF
4		EMPLOYMENT.
5	A.	My name is John Stuart McMenamin. I am Director of Forecasting at Itron Inc.
6		("Itron"), 12348 High Bluff Drive, Suite 210, San Diego, CA 92130.
7	Q.	ON WHOSE BEHALF ARE YOU TESTIFYING?
8	A.	I am testifying on behalf of CenterPoint Energy Houston Electric, LLC
9		("CenterPoint Houston" or "Company").
10	Q.	PLEASE DESCRIBE YOUR EDUCATIONAL BACKGROUND AND
11		PROFESSIONAL EXPERIENCE.
12	A.	I received my undergraduate degree in Mathematics and Economics from
13		Occidental College in Los Angeles, California in 1971. My post graduate degree
14		is a Ph.D. in Economics from the University of California, San Diego in 1976. I
15		have worked in the fields of energy forecasting and load research since 1976 and
16		have consulted with many of the major electric and gas utilities in North America.
17		In the 1980's and early 1990's, my work focused on end-use modeling and I was
18		the principal investigator for the Electric Power Research Institute end-use
19		modeling programs. More recently, my work has focused on methods that combine
20		econometric and end-use concepts. For the last 16 years, I have been employed by
21		Itron, and I am currently Director of the Forecasting and Load Research Solutions
22		group at Itron. Additional details are available in my resume, which is attached to
23		this testimony as Exhibit JSM-1.

### Q. PLEASE DESCRIBE YOUR DUTIES AS DIRECTOR OF FORECASTING AT ITRON.

3 A. For the last 15 years, I have been employed by Itron as Director of the Forecasting 4 Solutions group. During this period, I have been in charge of development for our 5 Automated Forecasting System which is used by many large system operators, like 6 the California ISO, Midwest ISO, and ERCOT. Also, I am responsible for Itron 7 products and services related to financial forecasting, including the Itron statistical 8 package (MetrixND) which is used by utilities (like CenterPoint Houston, Oncor, 9 CPS, TNMP, Xcel Energy, and Entergy) to forecast and analyze customers, sales, 10 revenues, and hourly loads. In addition to product design and algorithm 11 development, I direct or contribute to consulting projects related to forecasting and 12 load research for utilities. For the last 10 years, I have been working with utilities 13 in North America to help them improve analysis and forecasting processes using 14 advanced metering system (AMS) data. The work that was conducted for 15 CenterPoint Houston is an example of this type of work.

16

#### II. <u>PURPOSE OF TESTIMONY</u>

17 Q. WHAT IS THE PURPOSE OF YOUR TESTIMONY IN THIS
18 PROCEEDING?

A. The purpose of my testimony is to present the methods and data that were used to
develop weather adjustments for the Company's filing, including adjustments for
monthly sales, customer demand, billing demand, class peaks, and class loads at
the time of CenterPoint Houston and ERCOT peaks. The estimates were developed
using AMS data for the CenterPoint Houston population of metered customers. My

testimony describes the organization and processing of the 15-minute AMS data,
 as well as the modeling and weather adjustment calculations.

## 3 Q. HAVE YOU PREVIOUSLY PROVIDED TESTIMONY BEFORE THE 4 COMMISSION?

5 A. Yes. I provided weather normalization testimony last year in the Texas New
6 Mexico Power Company ("TNMP") rate case, Docket No. 48401.

### 7 Q. WHY DO UTILITIES MAKE WEATHER ADJUSTMENTS AS PART OF 8 RATE CASE FILINGS?

9 A. Utilities make weather adjustments to normalize energy usage patterns in the test 10 year. By looking at weather data from recent years, we can construct a test year 11 weather pattern that is representative of typical conditions. This insures that rates 12 are not based upon the specific and possibly uncharacteristic weather pattern that 13 occurred in one particular year. This is especially important in a year like 2018 14 which had weather much colder than normal in some winter months and weather 15 that was warmer than normal in the summer months.

#### 16 Q. ARE THE TYPES OF WEATHER ADJUSTMENTS YOU DISCUSS IN

- 17 YOUR TESTIMONY TYPICAL FOR UTILITIES IN RATE CASES?
- A. Yes. CenterPoint Houston and other utilities use weather adjustments, including
   adjustments for monthly sales, customer demand, billing demand, class peaks, and
   class loads at the time of Company and ERCOT peaks, when designing proposed
   rates. These adjustments are reasonable and necessary to prepare rates based on
   energy usage patterns that reflect typical conditions.

# Q. ARE THERE IMPORTANT DIFFERENCES BETWEEN THE WEATHER ADJUSTMENTS YOU RECOMMEND IN THIS PROCEEDING AND THOSE MADE IN PAST CENTERPOINT HOUSTON RATE CASES?

4 Yes. There are two notable differences. First, we are able in this proceeding to use A. 5 advanced meter data that was not yet available when preparing prior cases. In 6 Docket No. 38339, CenterPoint Houston's last rate case, the Company had to use a 7 small statistical sample of customers to estimate hourly usage patterns for each 8 customer class and complex monthly billing data for energy modeling. Today, with 9 advanced meters fully deployed, we can see actual customer demand for every 15-10 minute interval in every day of every month. These data support exact calculation 11 of daily energy, daily peaks, and daily coincident loads at the time of system peaks, 12 eliminating the statistical uncertainty from sample data. The availability of 13 complete and more granular interval data supports energy and peak adjustment 14 models that are more powerful and accurate than was possible in past rate cases.

A second difference in this proceeding is that we are defining "normal" weather based on a 20-year average instead of a 30-year average, which CenterPoint Houston used in its past few rate cases. Based on industry surveys, the utility industry has shifted to a 20-year average as the most frequently used period for defining normal weather.

## 20 Q. DO YOU SPONSOR ANY SCHEDULES IN THE RATE FILING 21 PACKAGE?

A. Yes. I am sponsoring Schedules related to weather adjustment of energy, class
 peak, class coincident loads, and customer demand. I sponsor or co-sponsor the

1	following	Rate	Filing	Package	("RFP")	schedules	including	the	associated
---	-----------	------	--------	---------	---------	-----------	-----------	-----	------------

2 workpapers:

3

4

5

6

7

8

Schedule II-H-1.2: Monthly Sales Data – This schedule provides the unadjusted and adjusted test year sales data and provides monthly weather adjustments for each class. My testimony relates to the weather data, modeling, and analysis used to calculate the weather adjustments presented in this schedule and other schedules listed below.

- 9 Schedule II-H-1.3: Unadjusted Test Year Load Data - This schedule provides the unadjusted Test Year data at the source 10 11 (busbar) and at the meter by rate class for each month of the Test 12 Year. Data include the following: Sum of customer maximum 13 demands (non-coincident); Class peak demand (non-coincident); 14 Class demand coincident with the CenterPoint Houston system peak demand; Class demand coincident with the ERCOT peak demand; 15 Energy usage; Monthly class coincidence and load factors. 16
- 17 Schedule II-H-1.4: Adjusted Test Year Load Data - This 18 schedule provides the adjusted Test Year data at the source (busbar) and at the meter by rate class for each month of the Test Year. Data 19 20 include the following: Sum of customer maximum demands (non-21 coincident); Class peak demand (non-coincident); Class demand 22 coincident with the CenterPoint Houston system peak demand; 23 Class demand coincident with ERCOT peak demand; Energy usage; 24 Monthly class coincidence and load factors.
- 25Schedule II-H-2.1: Model Information This schedule provides26descriptive information, definitions, and statistics related to27statistical models used to estimate weather adjustments to class28sales, class peaks, and class demand. The schedule also provides a29complete listing of the model spreadsheet files that are provided as30exhibits.
- 31 Schedule II-H-2.2: Model Data - This schedule provides 32 information about the structure of weather adjustment model 33 spreadsheet exhibit. There is one file per model, and each file 34 includes a complete listing of all data used in the model as well as 35 model coefficients and statistics, model predicted values and 36 residuals, and model statistics. Schedule II-H-2.2 lists the 37 worksheet tabs in each file and provides a description of the contents 38 of each tab.
- 39Schedule II-H-2.3: Model Variables This schedule provides40additional variable definitions for daily weather variables

1 constructed from daily heating degree and daily cooling degree 2 variables, as well as lagged daily weather variables, and weather 3 variables that are interacted with seasonal variables and day type 4 variables. An extension of this schedule (II-H-2.3-1) provides the 5 weights used for each class to combine low-powered, medium-6 powered, and high-powered heating degree (HD) and cooling 7 degree (CD) variables into the CDSpline and HDSpline variables 8 used in the energy and peak weather adjustment models.

9 Schedule II-H-4.1: Revenue Impact Data – This schedule 10 provides unadjusted and adjusted billing determinants. These data 11 are on a billing cycle bases and include weather adjustments to 12 revenue month sales (KWh) and customer demand (KVA), 13 customer billing demand (KVA), and customer load at the time of 14 the four ERCOT system peak days.

15Schedule II-H-5.1: Weather Station Data – This schedule16provides actual and normal monthly Heating Degree Days ("HDD")17and Cooling Degree Days ("CDD") for each of the three National18Oceanic and Atmospheric Administration ("NOAA") weather19stations used in the weather normalization analysis. It also provides20weighted monthly CDD and HDD values for CenterPoint Houston.

21Schedule II-H-5.2: Adjusted Weather Station Data – This22schedule provides actual and normal monthly Heating Degree Day23(HDD) and Cooling Degree Day (CDD) values computed for24individual billing cycles in each month and then combined across25cycles. The cycle calculations assume equal weight for each cycle.

#### 26 Q. HOW DOES YOUR TESTIMONY RELATE TO THAT OF OTHER

- 27 WITNESSES IN THIS PROCEEDING?
- 28 A. My testimony explains how CenterPoint Houston adjusts energy usage, class peak
- 29 demands, and billing determinants to reflect normal test-year weather. Company
- 30 witness Matt Troxle explains how the adjusted weather data are used to design

31 rates.

1		III. <u>UNADJUSTED TEST YEAR DATA</u>
2	Q.	PLEASE EXPLAIN THE SIGNIFICANCE OF UNADJUSTED TEST-YEAR
3		DATA.
4	A.	Unadjusted test-year data is the starting point for weather adjustment calculations.
5		It is used to estimate models that relate actual energy usage to actual weather
6		conditions in the test year. As described later in my testimony, these models are
7		then used to calculate weather adjustments and adjusted energy usage. The adjusted
8		energy use estimates are then used to compute revenues based on proposed rates.
9	Q.	PLEASE DESCRIBE THE PROCESS FOR DETERMINING THE
10		UNADJUSTED TEST YEAR LOAD DATA FOR CENTERPOINT
11		HOUSTON AS PROVIDED IN SCHEDULE II-H-1.3.
12	A.	The process starts with 15-minute AMS data for the population of about 2.3 million
13		CenterPoint Houston customers. CenterPoint Houston provided aggregated
14		interval data for each class for 2015 through 2018. In addition to 15-minute
15		consumption, the number of customers included in each 15-minute calculation was
16		provided.
17		In addition to the AMS data, the Company provided monthly billing data
18		for each class, including the number of customers, billing month energy, actual
19		monthly customer demand, monthly billing demand, and ERCOT monthly 4CP
20		values for the larger IDR classes.
21	Q.	PLEASE DESCRIBE THE STEPS IN PROCESSING THE 15-MINUTE
22		DATA.
23	A.	The 15-minute data for KWh and number of customers were provided for each
24		class. The classes are:

1		1. RS – Residential
2		2. SVS – Small secondary voltage
3		3. SVS_IDR – Small secondary voltage with IDR meter
4		4. SVL – Large secondary voltage
5		5. SVL_IDR – Large secondary voltage with IDR meter
6		6. PVS – Primary voltage
7		7. PVS_IDR – Primary voltage with IDR meter
8		8. TVS – Transmission voltage with IDR meter
9		9. SLS – Street lighting secondary voltage
10		10. MLS – Other lighting secondary voltage
11		The KWh and customer data series were inspected graphically in line charts to
12		examine trends, shifts, and spikes in the data. Also, the KWh data were aggregated
13		and compared to CenterPoint Houston system load data.
14	Q.	PLEASE EXPLAIN ANY ADJUSTMENT TO THE TEST YEAR LOAD
15		DATA.
16	A.	No adjustments were made to the test year load data.
17	Q.	PLEASE DESCRIBE THE AMS AND IDR 15-MINUTE DATA.
18	A.	15-minute data were provided for 2015 through 2018. These data were used to
19		calculate daily energy, daily class peaks, and class loads coincident with
20		CenterPoint Houston and ERCOT daily peaks. Definitions of the daily variables
21		follow:
22 23 24		Daily energy. Daily energy was computed by adding the KWh values for the 96 intervals in each day. These totals were divided by 1000 to convert to MWh.

- 1Daily class peaks. For each day, class peaks were identified as the2maximum of the 15-minute intervals for that day (in KWh)3multiplied by 4 to get a KW equivalent value and divided by 10004to get a MW equivalent value.
- 5 Coincident loads. On each day, the intervals for the CenterPoint 6 Houston system peak and ERCOT peak on that day were identified, 7 and the class loads for those intervals were extracted and multiplied 8 by 4 to get a KW equivalent value and divided by 1000 to get a MW 9 value.
- 10 An example of the data is provided in the following two panels. The first panel
- 11 shows data for the residential class in January. The date and time for the ERCOT
- 12 peak interval, the Company peak interval, and the residential class peak are
- 13 identified.

14

1	and monthly load factors and diversity factors. The daily data are also used to
2	estimate weather adjustment models for daily energy, daily class peak loads, and
3	loads coincident with CenterPoint Houston and ERCOT daily peaks.

In addition to the aggregated 15-minute interval data, monthly non coincident customer demand data were provided for each class for the months in 2018. To compute this value for a month, the maximum 15-minute interval in the month was located for each customer. These non coincident maximum customer demand values were then summed across all customers in each class.

### 9 Q. PLEASE EXPLAIN THE DATA USED TO IDENTIFY THE INTERVALS 10 FOR COINCIDENT PEAK CALCULATIONS.

A. ERCOT 15-minute load data were used to identify the time of the ERCOT peak
interval each day. Similarly, settlement data for CenterPoint Houston were used to
identify the time of the daily peak interval for the sum of CenterPoint Houston
customer loads on each day. Once the peak intervals were identified for each day,
the load for those intervals was extracted for each of the classes into a daily series
for that class.

#### 17 Q. HOW WERE LOSS FACTORS APPLIED TO THE AMS INTERVAL DATA

#### 18 TO DETERMINE ENERGY AND PEAK LOADS AT THE SOURCE?

A. AMS data is measured at the customer meter. To inflate these measured values for
 transmission and distribution losses, we applied distribution loss factors (DLF) and
 transmission loss factors (TLF) based on 15-minute loss factor data from ERCOT.
 The Company has two distribution loss factor categories, one for loads at secondary
 voltage and one for loads at primary voltage. For both categories, ERCOT
1		calculates distribution loss factors for each 15-minute interval based on the ERCOT
2		load in that interval.
3		The DLF were applied to all classes except Transmission. The TLF were
4		applied to all classes. For all classes except Transmission, the formula for each 15-
5		minute interval is:
6		Load@Source = Load@Meter * (1+DLF) * (1+TLF)
7		For the transmission class, the form is the same but the term with DLF is excluded.
8		The 15-minute data for Load@Source and the 15-minute data for
9		Load@Meter were then used to compute loss factor multipliers for daily and
10		monthly energy, daily and monthly class peaks, and daily and monthly coincident
11		peaks.
12		IV. WEATHER ADJUSTMENT MODELS FOR ENERGY
13	Q.	PLEASE EXPLAIN THE MODELING PROCESS USED TO CALCULATE
14		WEATHER ADJUSTMENTS FOR DAILY ENERGY.
15	A.	To adjust test-year energy, we start with models of actual energy usage for each
16		day of the test year. The models are used to calculate daily weather adjustments
17		for each day. The daily adjustments are added across days in the month to get
18		calendar month energy adjustments. The daily adjustments are added across days
19		in monthly billing cycles to get revenue month energy adjustments. The process
20		begins with a review of daily AMS data for each class. As an example, the
21		following figures show scatter plots of daily energy versus daily average
22		temperature for the residential (RS) and large secondary (SVL) classes. These two
72		classes account for more than 90% of the total weather adjustment for the test year.

12

In the charts, each point is one day. The charts show data for 2015 through 2018, so there are over 1,400 data points in each chart. The Y-axis is daily energy (computed from the 15-minute AMS data) in MWh. The X-axis is daily average temperature, computed from the hourly temperature values for the three weather stations related to the CenterPoint Houston service area. The points are color coded, with weekdays as blue circles, Saturdays as orange triangles, Sundays as red diamonds, and Holidays as green squares.

10 The charts show us where weather starts to matter on the warm side (about 11 65 for RS and about 60 for SVL). It also shows that not all degrees are equal and 12 that the early degrees cause a much weaker lift in daily energy than the more 13 extreme degrees. Finally, it shows a very strong heating response on the cold side 14 for RS and SVL classes, starting at about 60 degrees in both cases.

For each class, the modeling process starts by quantifying the nonlinear shape of the weather response using a preliminary regression to determine the relative strength of low-powered, medium-powered, and high-powered degrees for that class. This is accomplished by including multiple Heating Degree and Cooling

1	Degree variables in the preliminary regression. On the cooling side, the coefficients
2	from this regression are then used to construct a cooling degree spline that combines
3	the successive cooling degree variables. On the heating side, the coefficients from
4	this regression are used to construct a heating degree spline that combines the
5	successive heating degree variables. I believe that the use of these spline variables
6	is an effective and accurate method for modeling the nonlinear relationship between
7	weather and customer load and for calculating weather adjustments for daily energy
8	and daily peak loads.

9 To illustrate this process, consider the following example for the residential 10 model. The preliminary regression for this class provides the following coefficients 11 on the cooling side.

12

Figure 5. Example of Preliminary Regression and Spline Weight Calculation

(1) Variable	(2) Estimated Coefficient	(3) Standard Error	(4) T Statistic	(5) Siope (KWh/Degree)	(6) Spline Weight
CD65	0.688	0.054	12.63	0.688	0.263
CD70	0.615	0.108	5.67	1.303	0.235
CD75	0.656	0.109	6.02	1.959	0.251
CD80	0.659	0.087	7.53	2.618	0.252

13 The estimated coefficients in column (2) are the incremental slopes for each 14 successive cooling degree variable. The models are estimated with daily KWh per 15 customer as the Y variable, so the unit of measurement for these slopes is daily 16 KWh per customer per degree. The first variable (CD65) adds about .69 KWh per 17 degree. Moving above 70 degrees, this jumps up by an additional .61 KWh per degree (for a total slope of 1.30). Moving above 75 degrees, we gain an additional 18 19 .66 KWh per degree (for a total slope of 1.96). Finally, moving past 80 degrees, 20 we gain an additional .66 KWh per degree (for a total slope of 2.62). In this case,

the cumulative slopes indicate that degrees past 80 (CD80) are the most high powered degrees.

The spline weights are computed from these values by dividing the estimated coefficients by the largest cumulative slope value in column 5. If all coefficients are positive, this normalizes the weights to sum to 1.0. For the residential coefficients shown above, the initial cooling variable for degrees above 65 (CD65) has a spline weight of .263 (computed as .688/2.618), indicating that these degrees have about 26% of the impact of the high-powered degrees. With these weights, the CD spline variable is computed as:

10 CDSpline = .263 \* CD65 + .235 \* CD70 + .251 \* CD75 + .252 \* CD80

11 The comparable heating degree spline variable is:

HDSpline = .324 \* HD60 + .262 \* HD55 + .143 \* HD50 + .271 \* HD45
Once constructed, the daily HDSpline and CDSpline series provide powerful
variables that are nonlinear in temperature and that capture the shape of the weather
response. These variables are used to estimate models that explain variations in
daily energy use per customer based on daily weather variations. As I will show
below, the estimated models are then used to compute daily weather adjustments
for the test year.

### 19 Q. DO THE MODELS FOR DIFFERENT CLASSES USE THE SAME 20 COOLING DEGREE AND HEATING DEGREE VARIABLES?

A. No. Each class is evaluated separately to determine which HD and CD variables
 should be included. Generally, as customers get larger, the balance point between
 heating and cooling moves to the left. For small customers, cooling typically begins

to show up at 65 and heating begins to show at 60 degrees. For larger customers,
 weather effects usually start at lower temperatures. For the largest customers,
 weather effects can be hard to detect. For example, for the largest CenterPoint
 Houston class (TVS) there was no detectable heating or cooling activity.

5 The following table shows the HD and CD weights that were estimated for 6 the different classes for purposes of modeling daily energy use. More details are 7 provided in Schedule II-H-2.3 which provides the weights that were used for energy 8 and peak models.

9

Figure 6. HD and CD Spline Weights for Daily Energy Models

PVS_IDR	1.000				0.343		0.298	0.359	-0.365	

#### 10 Q. PLEASE EXPLAIN THE WEATHER ADJUSTMENT MODELS AND HOW

#### 11 THE SPLINE VARIABLES ARE USED IN THESE MODELS.

A. For energy and class peak demands, the weather adjustment models are daily
 models. The models include a constant term and a variety of daily calendar
 variables as well as the HDSpline and CDSpline variables. The calendar variables

are:

15

16

17

18

19

- Monthly binary variables for January through November (December excluded)
- Day of the week variables for Monday through Sunday (Wednesday excluded)
- Specific holiday variables for holidays from New Year's day through
   Christmas

1	<ul> <li>Annual binary variables to account for changes in use per customer</li> </ul>
2	• Class specific binary variables to account for irregular data
3	In addition to the HDSpline and CDSpline variables, additional weather interaction
4	variables are included in some of the models.
5 6	• Two-day weighted lag of HDSpline and CDSpline variables with 85%/15% weights
7 8	• Binary variable for weekend and holidays interacted with HDSpline and CDSpline
9	• Spring day variable interacted with HDSpline and CDSpline
10	• Fall day variable interacted with HDSpline and CDSpline
11	The full set of estimated models is included in the working papers filed with
12	this testimony. As an example, the following table provides the estimated
13	coefficients for the residential (RS) daily energy model with a first order
14	Autoregressive term (AR1).
15	The coefficients that matter for the weather adjustment are the last 10
16	variables, five for heating and five for cooling. These estimated coefficients all
17	give weather responses in units of KWh per customer per full powered heating
18	degree of per full powered cooling degree. For the residential model, the main
19	Spline variables have very strong statistical significance (T statistics greater than
20	40), and the lag and interaction variables are also significant (T statistics greater
21	than 2) with the exception of the Spring HDD slope shift which as a T statistic of -
22	1.69.
23	The LagHD and LagCD variables capture the carryover effect of prior day
24	temperatures onto the current day. For example, for the residential model, the
25	lagged effect for heating is about .34 KWh per degree, which is about 28% of the

1	same-day coefficient on HDSpline (1.24 KWh per degree). For cooling, the lag
2	effect is about .40 KWh per degree, which is about 17% of the same-day coefficient
3	on CDSpline (2.41 KWh per degree).

The weekend interactions (WkEndHD and WkEndCD) allow the weather response to be different for weekend days and holidays than it is for weekdays. For residential heating, the HDSpline slope is estimated to be about .15 KWh per degree smaller on weekend days than it is on weekdays. For residential cooling, the CDSpline slope is estimated to be about .04 KWh per degree bigger on weekend days than it is on weekdays.

For heating, the FallHD variable allows weather response to be different for months leading into winter and the SpringHD variable allows weather response to be different for the months following winter. The estimated coefficients suggest a weaker response for residential heating on both sides of the winter months. The Fall response is estimated to be .23 KWh per degree (or 19%) weaker than the Winter response. The Spring response is estimated to be .12 KWh per degree (or 10%) weaker than the Winter response.

AR1	AR(1)	0.576	0 022	26.010		

For cooling, the SpringCD variable allows weather response to be different for months leading into Summer and the FallCD variable allows weather response to be different for the months following Summer. The estimated coefficients suggest a slightly reduced response for residential cooling on both sides of the Summer months. The Spring response is estimated to be .27 KWh per degree (or 11%)

1	weaker than the Summer response. The Fall response is estimated to be .34 KWI
2	per degree (or 14%) weaker than the Summer response.

These coefficients are used to compute daily weather impacts and weather adjustments. The weather impact is the difference between the model predicted value with actual weather and the model predicted value with normal weather. If the weather impact is positive (actual weather was extreme), the weather adjustment will be negative. If the weather impact is negative (actual weather was mild), the weather adjustment will be positive.

9 As an example of mild weather, February of 2018 was not as cold as normal. 10 As a result, heating energy was less than expected, so a positive weather adjustment 11 for heating was required to bring heating energy back up to normal levels in this 12 month.

As an example of extreme weather, January of 2018 was colder than normal. As a result, heating energy was much higher than expected, so a negative weather adjustment for heating was required to bring heating energy down to normal levels in this month. On the cooling side, the summer months (especially May, June and July) of 2018 were all warmer than normal. As a result, there was extra cooling energy use, and negative adjustments were required to bring cooling energy down to normal levels.

## Q. AN AUTOREGRESSIVE ERROR TERM HAS BEEN INCLUDED IN THE WEATHER ADJUSTMENT MODELS. DOES THIS MAKE A DIFFERENCE?

A. Before adding the autoregressive term, it is important to build a strong static model
to ensure the right functional form exists. Otherwise, the autoregressive term could
disguise a specification problem. In the working papers, both the static model
results (without the AR1 term) and the dynamic model results (with the AR1 term)
are provided. For example, the following provides the residential model coefficient
estimates for the HD and CD variables from both specifications.

10

Figure 8. RS Daily Energy Model Weather Coefficients

		Stati	c Modei (No	AR1)	Dynamic Model (with AR1)			
Туре	Variable	Coefficient	Std Error	T-Stat	Coefficient	Std Error	T-Stat	
Heating	HDSpline	1 300	0 030	42.747	1.240	0 028	43 663	
Heating	LagHD	0.343	0.026	13.312	0.341	0.024	14.394	
Heating	WkEndHD	-0.206	0.039	-5.247	-0.151	0.031	-4.954	
Heating	SpringHD	-0.184	0.063	-2.923	-0.123	0.073	-1.689	
Heating	Falind	-0.212	0.058	-3.668	-0.232	0.062	-3.710	
Cooling	CDSpline	2 393	0.033	72.117	2.408	0.030	80.346	
Cooling	LagCD	0.370	0.031	11.933	0.400	0.028	14.509	
Cooling	WkEndCD	0.029	0.021	1.363	0.041	0.017	2.403	
Cooling	SpringCD	-0.110	0.081	-1.372	-0.270	0.081	-3.333	
Cooling	FallCD	-0.168	0.065	-2.591	-0.342	0.072	-4.756	

11 The coefficient pattern from the two specifications is consistent, and all coefficient 12 estimates from the two specifications are well within two standard errors of each 13 other in most cases. For example, the CDSpline coefficient is 2.393 KWh per 14 degree in the static model and 2.408 KWh per degree in the model with the AR1 15 term. Both parameters are strongly statistically significant (t-statistics > 70). The 16 standard error in both models is about .03, so the two slopes are basically the same 17 in a practical sense and in a statistical sense. This coefficient stability is the 18 signature of a strong well specified model.

Both sets of models for all classes are included in the working papers filed with this
 testimony. The weather adjustments presented in the Schedules are from the
 models with the AR1 terms, but the results would not differ materially if the static
 models are used.

### 5 Q. HOW WELL DO THESE MODELS EXPLAIN THE DAILY VARIATION 6 IN ENERGY?

# A. Generally, these models are very strong and explain the daily variations with good accuracy. For example, the following chart shows the actual and predicted daily energy values for the residential model for 2018.

In the chart, the red line is the actual daily energy computed from the 15minute AMS data and the blue line is the model predicted values. Clearly the model
works extremely well throughout the year.

13

14

### 15 The following provides the model statistics for the static (without AR1) and16 dynamic (with AR1) residential models.

Residential (RS) Energy Model Statistics	Static Model (No AR1)	Dynamic Model (With AR1)
Adjusted Observations	1449	1449
Deg. of Freedom for Error	1404	1403
R-Squared	0.985	0.990
Adjusted R-Squared	0.985	0.989
AIC	1.053	0.671
BIC	1.217	0.839
Std. Error of Regression	1.67	1.38
Mean Abs. Dev. (MAD)	1.32	1.05
Mean Abs. % Err. (MAPE)	3.87%	3.10%
Durbin-Watson Statistic	0.894	2.067

Figure 10. RS Energy Model Statistics

2 The quality of the model fit is excellent with mean absolute percent error (MAPE) 3 values of 3.87% for the static model and 3.10% for the dynamic model. The 4 Durbin-Watson statistic provides an indicator of first order autocorrelation. This 5 statistic ranges from 0 to 4 and values that are near 2.0 indicate absence of first 6 order autocorrelation. As values decline toward 0.0, this provides increasing 7 evidence of positive autocorrelation. As values rise toward 4.0, this provides 8 increasing evidence of negative autocorrelation. For the static model, the value of 9 .89 indicates strong positive autocorrelation. With the AR1 correction there is no 10 indication of first order autocorrelation (as indicated by the Durbin-Watson statistic 11 of 2.07).

12 The following table provides the daily energy model summary statistics for 13 all of the weather sensitive classes. As this shows, the model fit for all classes is 14 strong, with MAPE values ranging between 1.1% and 3.1%.

#### V. WEATHER ADJUSTMENT MODELS FOR CLASS PEAKS AND CP VALUES

3 4

2

### Q. PLEASE EXPLAIN THE MODELING PROCESS USED TO CALCULATE

#### 5 WEATHER ADJUSTMENTS FOR CLASS PEAK MODELS.

6 A. In addition to adjusting energy data to reflect normal weather, for rate design 7 purposes we also need to know about peak loads for each customer class (class peak 8 model), and to know about class loads at the time of overall system peak loads 9 (coincident peak (CP) model). The daily class peak models are similar to the daily 10 energy models, except daily class peak load is the variable that is explained instead of daily energy. As examples, the following figures show scatter plots of daily 11 12 class peak vs daily average temperature for the residential (RS) and large secondary 13 (SVL) classes.

#### Figures 12 and 13. Daily Class Peak vs. Daily Average Temperature for RS and SVL

These graphs show weather response patterns for daily class peaks that are similar to the daily energy patterns. However, there are some differences, and as a result, we estimated a different set of HD and CD weights for the class peak and coincident 6 peak models. These weights are shown in the following table.

7

3

4

5

1

2

Figure 14. HD and CD Spline Weights for Class Peak Models

ſ	Γ	leating Deg	ree Weigh	ts		Cooling Degree Weights

PVS_IDR	1.000				0.449	I .	0.551		-0.251

8 The class peak models contain the same set of explanatory variables discussed 9 above for the daily energy models. The working papers filed with this testimony 10 contain spreadsheets that show all of the data used in the models as well as estimated coefficients, model statistics, and actual and predicted values. 11 12 Spreadsheets are provided for static models and for dynamic models with AR1 13 adjustments. The models with AR1 adjustments are used to compute the weather 14 adjustments presented in the Schedules.

Like the daily energy models, the class peak models are very strong and
 explain most of the daily variation in class peaks. For example, the following chart
 shows the actual and predicted values for the residential daily class peaks in 2018.

The class peak models have errors that are slightly larger than for the energy
models. The mean absolute percent errors for these models range from 1.3% (Small
Secondary) to 6.2% (Residential). As with the energy models, weather slopes are
well defined and strongly significant.

### 10 Q. HOW DO THE COINCIDENT PEAK (CP) MODELS DIFFER FROM THE

#### 11 CLASS PEAK MODELS?

4 5

12 A. Two sets of daily CP models are estimated, one using load at the time of the daily 13 CenterPoint Houston peak and the other using load at the time of the daily ERCOT 14 peak. The CP models use the same set of weather variables and the same model 15 specifications that are used in the daily class peak models. The model estimation 16 results are similar to the daily class peak models in terms of weather parameters 17 and model fit statistics. The full set of model results with and without AR1 terms 18 is included in the working papers filed with this testimony.

2 Q. PLEASE EXPLAIN THE MODELS USED TO WEATHER ADJUST

3 CALENDAR MONTH CUSTOMER DEMAND.

11 12

A. Customer demand for a calendar month is the sum of the individual customer
maximum demands in the month. Customer demand differs from class peak
demand since individual customers have maximum demand values on different
days in the month and at different times of day. This load diversity implies that
customer demand in a month is a bigger number than the class peak demand in the
month. The following shows the monthly customer demand and class peak data for
2018 for the residential (RS) and large secondary (SVL) classes.

For the residential (RS) class, the sum of the monthly customer demand values is almost three times as large as the monthly class peaks. For the large secondary (SVL) class, the sum of the individual customer demands is about 60% larger than the class peaks. Despite the larger scale, there is less variation from month to month in the customer demands as measured by the standard deviations of the monthly values. For example, the standard deviation of the RS demand values is about 40% of the standard deviation of the class peak values.

1	For the customer demand models, data are only available for 2018,
2	providing 12 monthly observations for each class. As a result of this limited sample
3	size, the weather response models are relatively simple. For the heating side, the
4	models include the largest value of HD55 in each month, representing the coldest
5	day. For the cooling side, the models include the largest value of CD70 for each
6	month, representing the hottest day.

The estimated model coefficients are shown below. Despite the small sample size, the estimated coefficients are statistically significant in almost all cases, as indicated by T-statistics greater than 2.0. The only exception is the coefficient for HD55 in the PVS\_IDR equation. This is consistent with the relatively weak response to cold weather for this class. The slopes are in terms of MW per degree, and the largest slopes are for the residential (RS) class and the large secondary (SVL) class.

14

Figure 18. Estimate	d Coefficients from	Calendar Month	Demand Models
---------------------	---------------------	----------------	---------------

	We	ighted MaxHi	)55	Weighted MaxCD70			
Customer Class	Coefficient	Std Error	T-Stat	Coefficient	Std Error	T-Stat	
Residentiai (RS)	68 66	17.13	4 01	115 31	23.50	4 91	
Secondary Voltage Smail (SVS-Non IDR)	1.21	0.22	5.58	1.87	6.30	6.31	
Secondary Voltage Large (SVL-Non IDR)	36.06	4.57	7.89	45 10	6 27	7.19	
Secondary Voltage Large (SVL-IDR)	3.77	1.58	2.25	28 43	2 30	12.35	
Primary Voltage Service (PVS-Non IDR)	0 68	0.16	4 28	1.09	0.22	4 97	
Primary Voltage Service (PVS-IDR)	0 37	0.49	074	5 2 3	0.68	7.72	

Because of the small sample size, the customer demand models were estimated without autoregressive error corrections. Inclusion of an AR1 correction would imply losing the first observation (Jan 2018), and this particular observation is critical to determining the response of customer demand to cold weather. Although the models are simple, they explain customer demand very well with mean absolute

- percent errors below 2% for all classes except the non IDR Primary (PVS) class,
   which had a MAPE value of 3.26%.
- In the working papers, we have provided spreadsheets that contain the data used to estimate these models as well as the estimated coefficients, model statistics, and actual and predicted values.
- 6 To calculate weather adjustments for calendar month customer demand, the 7 estimated models are used to simulate predicted customer demands using normal 8 values for the coldest (HD55) and hottest (CD70) days in each month. The 9 difference between the model predicted value with actual inputs and the model 10 simulated value with normal inputs is the weather impact for each calendar month. 11 These impacts are subtracted from the actual demands to give the weather adjusted 12 calendar month demand estimates.

## 13 Q. PLEASE EXPLAIN MODELS USED TO WEATHER ADJUST REVENUE 14 MONTH CUSTOMER DEMAND.

A. Revenue month customer demand models are estimated for only two classes, large
secondary (SVL) and primary (PVS). These are the only two classes that use actual
customer demand directly as a billing determinant.

18 The actual demand value in a revenue month for a customer corresponds to 19 the largest load that occurs during the days of the billing cycle to which the 20 customer is assigned. Not only are customer demands occurring on different days 21 and at different times, but the set of days included is different for each of the 21 22 billing cycles. In addition, the number of billing cycles included in a month can 23 vary. For example, in 2018, December and September had only 19 contributing

cycles. In contrast, October and August had 23 contributing billing cycles. A
 difference of 4 cycles would imply an expected 20% variation in energy usage if
 energy use was flat across all days.

The models are estimated using billing data from the middle of 2015 through 2018. To account for customer growth, the models are estimated based on billing demand per customer. To account for the difference in the number of cycles contributing to each month, the demand per customer values are further normalized to represent 21 full cycles. In equation form, the Y variable in the revenue month demand equation for a class is:

Y(m) = (DemandKVA(m)/Customers(m)) \* (21/NCycles(m))

10

In this expression DemandKVA is the sum of the customer maximum demand values in KVA and NCycles is the number of billing cycles contributing to revenue in each billing month. Prior to 2018, the cycle adjustment is different for AMS customers and IDR customers. Starting in January 2018, the two billing cycle schedules were converged.

As with the calendar month customer demand, the actual demand values for a revenue month are larger than monthly class peak values, reflecting the diversity in the timing of the individual customer peaks. For example, for the large secondary (SVL) class, the monthly class peaks in 2018 averaged about 3,400 MW, whereas the average of the actual demand values in the revenue months was close to 6,000 MVA.

Billing cycles for a revenue month span days in the current month and prior
 calendar months. For example in January, typically about half of the cycle energy

1	comes from days in December and half comes from days in January. To reflect this,
2	explanatory variables for a month are calculated as a weighted average of the
3	current and prior month values with 50/50 weights. The first explanatory variable
4	is the monthly class peak normalized by the number of customers in each month.
5	The weighted variable is:
6	Wgt_NCP_PerCust(m) = .5 * NCP_PerCust(m) + .5 * NCP_PerCust(m-1)
7	The model is estimated with the actual weighted class peak values and is later
8	simulated with the weather adjusted weighted class peak values.
9	The customer demands are not necessarily expected to be explained
10	completely by the class peak values, so direct weather variables are also included.
11	To represent the impact of coldest day in each month, the maximum value of the
12	heating degree variable with base temperature 55 is included. The two-month
13	weighted value is computed as follows:
14	$Wgt_MaxHD55 = .5 * MaxHD55(m) + .5 * MaxHD55(m-1)$
15	where MaxHD55(m) is the largest of the daily HD55 values in month m.
16	Similarly, to represent the impact of the hottest day in each month, the
17	maximum value of the cooling degree variable with base temperature 70 is
18	included. The two-month weighted value is computed as follows:
19	$Wgt_MaxCD70 = .5 * MaxCD70(m) + .5 * MaxCD70(m-1)$
20	where MaxCD70(m) is the largest of the daily CD70 values in month m.
21	The estimated model for the large secondary (SVL) class is shown below.
22	Actual and predicted values from the monthly model are also shown along with key
23	model statistics.

	1	Standard	T	1	
Variable	Coefficient	Error	Statistic	Units	Definition
CONST	29.629	3.147	9.41		
SVL_Wgt_NCP	0 520	0.165	3.15	KWh	Two-month weighted class peak per customer
Wgt_MaxHD55	0 193	0.031	634	DegF	Two-month weighted maximum HDSS
Wgt_MaxCD70	0.178	0.094	188	DegF	Two-month weighted maximum CD70
AR(1)	0 399	0.160	2.50		

Figures 19 and 20. Revenue Month Billing Demand Model for SVL

In the working papers, spreadsheets are provided for the static and dynamic versions of the model for each class. The spreadsheets contain all data used to estimate these models as well as the estimated coefficients, model statistics, and actual and predicted values. Although the models are very simple, they have strong predictive power, with mean absolute percent errors of 1.9% for SVL and 3.1% for PVS.

8 To calculate weather adjustments for the revenue month demands, the 9 models are used to simulate predicted demands using weather adjusted values of 10 the current and prior month class peaks and normal values for the current and prior 11 month weather variables. The differences between the model predicted values with 12 actual inputs and the model simulated values with normal inputs are the weather 13 impacts. These impacts are subtracted from the actual values to give the weather 14 adjusted revenue month demand estimates.

1	Q.	PLEASE EXPLAIN THE APPROACH USED TO ESTIMATE WEATHER
2		IMPACTS FOR REVENUE MONTH BILLING DEMAND.
3	A.	For each customer, monthly billing demand is as large or larger than actual demand,
4		reflecting the "ratchet" calculation, which sets billing demand to the larger of the
5		actual demand in a month and 80% of the largest demand in the prior 11 months.
6		For example, in 2018, monthly billing demands for SVL averaged about 6,500
7		MW, which is about 9% above the average monthly actual demand for the SVL
8		class.
9		There are four classes that are weather sensitive and that include billing
10		demand as a billing determinant.
11		• SVL which has actual demand and billing demand as billing determinants
12		• PVS which has actual demand and billing demand as billing determinants
13		• SVL_IDR which has billing demand and 4CP as billing determinants
14		• PVS_IDR which has billing demand and 4CP as billing determinants
15		For SVL and PVS, we already have models for the actual demand, as discussed
16		above. For these classes, the billing demand model is very simple and specifies
17		billing demand as a function of actual demand. This allows the actual demand
18		weather impacts to be passed through to the billing demand. For the IDR classes,
19		actual demand data were not available. As a result, the billing demand is modeled
20		directly for these classes.

## Q. PLEASE EXPLAIN THE MODELS USED TO ESTIMATE WEATHER IMPACTS FOR REVENUE MONTH BILLING DEMAND FOR SVL AND PVS CLASSES.

4 A. The SVL and PVS billing demand models are estimated with billing demand per 5 customer adjusted for cycles as the variable to be explained and actual demand per customer adjusted for cycles as the explanatory variable. Results for the SVL and 6 7 PVS models are summarized below. As shown, the coefficients on actual demand are strong and well defined, as evidenced by small standard errors and very high T 8 9 statistics. The elasticities are .59 for SVL and .89 for PVS, which suggests that ratchets play a relatively weak role for PVS bills. Finally, the models are very 10 11 precise with average errors of .35% for SVL and 1.84% for PVS.

12

Figure 21. Slopes and Statistics for SVL and PVS Billing Demand Models

Variable	Actual Demand Slope	Standard Error	T Statistic	Elasticity	Mean Abs % Error	Durbin Watson
Large Secondary (SVL)	0.682	0.027	25.42	0.63	0.35%	2.02
Primary (PVS)	0.994	0.057	17.32	0.89	1.84%	1.26

To calculate weather adjustments for billing demand, the models are used to simulate billing demands using weather adjusted revenue month demand. The differences between the model predicted values with actual demands and the model simulated values with weather adjusted demands are the weather impacts. These impacts are subtracted from the billing demand values to give the weather adjusted revenue month demand estimates.

# Q. PLEASE EXPLAIN THE MODELS USED TO ESTIMATE WEATHER IMPACTS FOR REVENUE MONTH BILLING DEMAND FOR SVL\_IDR AND PVS\_IDR CLASSES.

A. The billing demand models for SVL\_IDR and PVS\_IDR take the same form as the
revenue month actual demand models for SVL and PVS. As described above, these
models have three inputs that are weighted across the current and prior months.
The inputs are (a) the weighted class peak per customer, (b) weighted HD55 for the
coldest days, and (c) weighted CD70 for the hottest days. The dependent variable
in these models is revenue month billing demand per customer adjusted for the
number of cycles.

11 The model for SVL\_IDR is shown below. In addition to the three weighted 12 variables, this model also includes a trinary variable (0, -1, 1) to account for billing 13 data irregularities in August and September of 2017.

1	In the working papers, spreadsheets are provided for the static and dynamic
2	versions of the model for each class. The spreadsheets contain all data used to
3	estimate these models as well as the estimated coefficients, model statistics, and
4	actual and predicted values. Although the models are very simple, they have strong
5	predictive power, with mean absolute percent errors of 1.4% for SVL_IDR and
6	2.2% for PVS_IDR.
7	To calculate weather adjustments for the revenue month demands, the
8	models are used to simulate predicted demands using weather adjusted values of

9 the current and prior month class peaks and normal values for the current and prior 10 month weather variables. The differences between the model predicted values with 11 actual inputs and the model simulated values with normal inputs are the weather 12 impacts. These impacts are subtracted from the actual billing demand values to 13 give the weather adjusted revenue month billing demand estimates.

14

#### VII. NORMAL WEATHER CALCULATIONS

### 15 Q. PLEASE DESCRIBE THE DATA AND PROCESS USED TO DEFINE 16 NORMAL WEATHER FOR THE TEST YEAR.

17 To perform daily weather adjustment calculations, it was necessary to define A. 18 normal daily weather. In order to represent normal weather for both energy and 19 peak calculations a "rank and average" approach was used. This was done with hourly weather data for the 20-year period between 1998 and 2017. In prior 20 21 decades, the common practice was to use a 30-year period for defining normal weather. Our most recent industry survey in 2017 indicates that a 20-year period 22 23 is now the prevalent practice. Accordingly, I recommended a 20-year period to 24 define normal weather in performing daily weather adjustment calculations as part

1	of my testimony in Texas New Mexico Power Company's ("TNMP") recent rate
2	case (Docket No. 48401). <sup>1</sup> Darryl Nelson, as witness for Oncor Electric Delivery
3	Company LLC for its recent rate case (Docket No. 46957), also recommended a
4	20-year period for the weather adjustment calculations. <sup>2</sup> Although both of these
5	cases settled, they reflect that the use of a 20-year period of weather data for the
6	weather adjustment calculations is consistent with current industry practice.
7	Steps in the approach to define normal weather are as follows:
8 9 10	1. Compute daily average temperature for each station and historical day as the average of the hourly values for that day. Stations are Houston International, Houston Hobby, and Sugarland.
11 12 13	2. Compute daily heating degree (HD) and cooling degree (CD) values for each station and each temperature base using the daily average temperature value for each historical day.
14 15	3. Combine average temperature, HD, and CD variables across stations using equal weights. The remaining operations are applied to the combined data.
16 17	4. Rank the daily data for each historical month and year by sorting the data from hottest to coldest based on the combined daily average temperature.
18 19 20	5. For each month, average the ranked data across the 20-year historical period. This gives an average hottest day, an average second hottest data, and so on through to an average coldest day for each month.
21 22 23 24 25	6. Assign the rank-and-average results to days in 2018 based on the weather order that actually occurred in 2018. For example, the coldest day in January 2018 will be assigned the value for the typical coldest day in January. Similarly, the hottest day in July 2018 will be assigned the value for the typical hottest day in July.
26	The results after the rank and average calculation (step 5 above) are shown in the
27	following chart. This chart shows the result of the process applied to daily average

<sup>&</sup>lt;sup>1</sup> Docket No. 48401, Direct Testimony of J. Stuart McMenamin, 1618. <sup>2</sup> Docket No. 46957, Direct Testimony of Darryl E. Nelson, 1531.

JAR.

5 This chart provides a clear picture of how actual and normal weather compare 6 within each month. For example, for January of 2018, the actual values are all 7 below the normal values. The coldest days are well below normal, and this will 8 imply significantly higher than normal heating loads on many days of the month. 9 In contrast, most days in February of 2018 were significantly warmer than normal. 10 This will imply higher than normal cooling loads on the warmest days and lower 11 than normal heating loads on the mild and colder days.

Jan

12 Most of the months in 2018 show warmer than normal temperatures. The exceptions are January (noted above), April, and November, all of which are cooler 13 14 than normal. For the summer months, June and July show the largest deviations 15 above normal, with August and September showing smaller deviations above 16 normal.

17 The following chart shows the data for 2018 after Step 6, in which normal 18 values are assigned to days based on the actual 2018 weather pattern. As before, 19 the red line shows actual daily average temperatures, and the green line shows the

assigned normal values. The blue line shows the daily deviations. A negative value for the blue line occurs when a day is colder than normal. A positive value for the blue line occurs when a day is warmer than normal. This is the way the modeling process sees the data for observations in 2018. The actual data (red line) are used to estimate models and to compute model predicted values with actual weather. The normal data (green line) are used to simulate models with normal weather.

1

2

3

4

5

6

7

Figure 25. Rank and Average Results Sorted by 2018 Daily Weather Pattern

8 As described earlier, the models are based on heating degree (HD) and cooling 9 degree (CD) values for various base temperatures. The following charts show the 10 monthly sum of the HD values, called Heating Degree Days (HDD) and the 11 monthly sum of CD values, called Cooling Degree Days (CDD). Both HDD and 12 CDD values are shown with a base temperature of 65 degrees.

13The CDD chart shows that the months of May through September all had14more than normal cooling degrees, with the biggest deviations in May, June, and15July. The HDD chart shows that the months of January, April, and November had16more than normal heating degrees, with the biggest deviation in January.

12

3 4

5 These results show heating and cooling degrees added across all the days in each 6 calendar month. For modeling class peaks, it is also useful to understand how the 7 most extreme weather in each month compares to the normal extreme values. The 8 rank and average calculation gives us a typical hottest day in each month and a 9 typical coldest day in each month. The following charts show the comparison of 10 these typical extremes and the actual hottest and coldest days in each month of 11 2018.

Understanding these charts helps to explain some of the results that are seen
in the demand models. For example, it is expected to see extra demand from
heating in January. Extra customer demand from cooling is expected in many

months, and even for winter months, like February. In November, both are seen, with increased cooling demands for some customers and increased heating demands for others. And in December, weak customer demands are expected, reflecting weak extremes on both the hot and cold side. This last observation will mainly apply to calendar month demand. Revenue month demands for the December billing month will be mixed, with stronger demands from the cycles with days in November spilling into the December revenue month.

6

7

8

More details on weather data are presented in Schedule II-H-5.1 and II-H-5.2.

1		VIII. SCHEDULES FOR TEST-YEAR SALES DATA
2	Q.	PLEASE DESCRIBE THE PROCESS FOR DETERMINING THE
3		WEATHER ADJUSTMENTS REPORTED FOR TEST YEAR MONTHLY
4		SALES IN SCHEDULE II-H-1.2.
5	A.	Weather adjustments to test year energy are computed using daily energy models
6		based on AMS data. Daily energy models are discussed earlier in the testimony
7		and include CD spline and HD spline variables that embody the nonlinear
8		relationship between temperature and daily energy. These variables appear in the
9		models directly and also interacting with weekend variables and seasonal variables
10		that allow the weather response to be different on different types of days.
11		Daily energy models are estimated with actual daily weather from 2015 to
12		2018. The estimated models are used to recalculate what daily energy would have
13		been with normal weather on each day. The difference between predicted values
14		with actual weather and predicted values with normal weather is the weather
15		impact. The weather impact is subtracted from actual sales to get adjusted daily
16		sales.
17		The daily weather impacts from the daily energy models are used to adjust
18		billed sales as reported on Schedule II-H-1.2. Billed sales data represent customer
19		usage over the billing cycles that contribute to each revenue month. For each cycle
20		that contributes to a revenue month, the daily weather impacts are summed across
21		the days in that cycle. These sums are then combined across cycles by assigning

23 cycles, these weights sum to one. In revenue months with less than 21 cycles, the

22

Direct Testimony of J. Stuart McMenamin CenterPoint Energy Houston Electric, LLC

an equal weight (1/21) to each cycle. In a revenue month that includes exactly 21

weights sum to less than one. In revenue months with more than 21 cycles, the
 weights sum to more than one.

## 3 Q. HOW DO THE REVENUE MONTH WEATHER ADJUSTMENTS IN II-H4 1.2 COMPARE TO THE CALENDAR MONTH WEATHER 5 ADJUSTMENTS FOR ENERGY IN II-H-1.3?

6 A. The adjustments follow the same general pattern, but there are some notable 7 differences. For example, calendar month April was a very mild month. This resulted in weak cooling loads and a positive weather adjustment. For the 8 9 residential class, we estimate that loads in calendar month April would have been 10 about 145 GWh higher with normal weather. In contrast, the billed sales in April reflect weather for days in March and April. Unlike April, March was much 11 12 warmer than normal, resulting in strong cooling loads and a negative adjustment 13 for most days. The net result when the daily adjustments are combined across the 14 April cycles is a residential adjustment that is close to zero (an upward adjustment 15 of 14 GWh). For some of the business classes, the sign of the weather adjustment in April changes, in that we are adjusting energy upward for calendar month April 16 17 but downward for billing month April.

18 The weather adjustments for energy are negative for the year as a whole for 19 both the calendar year and the revenue year. This is true for all classes, and reflects 20 the combination of extra heating from colder than normal weather in January and 21 November and extra cooling from warmer than normal weather in most of the 22 remaining months. For all classes, the billed sales annual adjustments are slightly 23 larger in absolute and percentage terms than the calendar year annual adjustments.

1	This reflects the fact that December of 2017 had relatively normal weather and did
2	not contribute much to adjustments in the January 2018 billing month. In contrast,
3	December of 2018 had mild weather, leading to positive weather adjustments in the
4	calendar month. On a cycle basis, about half of these positive adjustments get
5	mapped to January of 2019, and therefore do not contribute to the adjustments for
6	2018 billed sales.
7	Annual impacts are summarized in the following table for the rate classes
•	

8 that have weather adjustments. For example, for the residential class, the annual
9 adjustment to billed sales is -1,578 GWh which is a 5.16% downward adjustment.
10 On a calendar year basis, the annual adjustment is -1,453 GWh, which is a 4.77%
11 downward adjustment.

12

Figure 30. Summary of Annual Weather Adjustments for 2018

	Calendar Year		Revenue Year	
Rate Class	GWh	Percent	GWh	Percent
Residential (RS)	-1,452.5	-4.77%	-1,578.0	-5.16%
Secondary Voltage Small (SVS-Non IDR)	-10.4	-1.04%	-11.6	-1.25%
Secondary Voltage Large (SVL-Non IDR)	-324.8	-1.80%	-361.2	-1.99%
Secondary Voltage Large (SVL-IDR)	-128.7	-0.90%	-135.9	-0.95%
Primary Voltage Service (PVS-Non IDR)	-6.0	-2.04%	-6.7	-2.29%
Primary Voltage Service (PVS-IDR)	-28.1	-0.72%	-28.8	-0.74%

Summed across all classes, the annual adjustment to billed sales is -2,122 GWh,
which is a downward adjustment of 2.33%. On a calendar year basis, the annual
adjustment is -1,951 GWh, which is a downward adjustment of 2.15%.

1		IX. SCHEDULES FOR TEST-YEAR LOAD DATA
2	Q.	PLEASE DESCRIBE THE PROCESS FOR DETERMINING THE
3		RESULTS FOR CUSTOMER MAXIMUM DEMAND AT THE METER
4		AND AT THE SOURCE PROVIDED IN SCHEDULE II-H-1.3.
5	A.	Customer maximum demand at the meter is computed from the AMS and IDR 15-
6		minute interval data for each customer. These values are then added across
7		customers to get the actual demand sum for each class in each calendar month.
8		Because the individual customer demand values come from different days
9		and different hours on those days, there is not a specific loss multiplier that is
10		appropriate to compute demand values at the source. The values at the source on
11		Schedule II-H-1.3 were computed using the distribution and transmission loss
12		multipliers for monthly energy.
13	Q.	PLEASE DESCRIBE THE PROCESS FOR DETERMINING THE
14		RESULTS FOR CLASS PEAK DEMAND AT THE METER AND AT THE
15		SOURCE PROVIDED IN SCHEDULE II-H-1.3.
16	A.	Class peak demand at the meter is computed directly from the 15-minute interval
17		data summed across customers in each class. Class peak demand at the source is
18		computed from class peak demand at the meter adjusted upward for distribution
19		and transmission loss factors. The loss factors for a month are the 15-minute loss
20		factors that apply for the class peak interval in that month.

1	Q.	PLEASE DESCRIBE THE PROCESS FOR DETERMINING THE
2		RESULTS FOR CLASS LOAD AT CENTERPOINT HOUSTON PEAK
3		PROVIDED IN SCHEDULE II-H-1.3.

A. CenterPoint Houston peak intervals are determined from 15-minute load data for
the CenterPoint Houston system. In each month, the class load in the peak interval
is extracted from the 15-minute interval data for that class. This is the class
coincident load at the meter.

8 Class load at the CenterPoint Houston peak interval at the source is 9 computed from the class load at the meter adjusted upward for distribution and 10 transmission loss factors. The loss factors for a month are the 15-minute loss 11 factors that apply at the time of the CenterPoint Houston peak in that month.

## 12 Q. PLEASE DESCRIBE THE PROCESS FOR DETERMINING THE 13 RESULTS FOR CLASS LOAD AT ERCOT PEAK PROVIDED IN 14 SCHEDULE II-H-1.3.

A. ERCOT peak intervals are determined based on 15-minute ERCOT load data
published by ERCOT. In each month, the class load in the peak interval is extracted
from the 15-minute AMS data for that class. This is the class coincident load at the
meter.

19 Class load at the ERCOT peak interval at the source is computed from the 20 class load at the meter adjusted upward for distribution and transmission loss 21 factors. The loss factors for a month are the 15-minute loss factors that apply at the 22 time of the ERCOT peak in that month.

1	Q.	PLEASE DESCRIBE THE PROCESS FOR DETERMINING TH
2		RESULTS FOR ENERGY USAGE AT THE METER AND AT TH
3		SOURCE PROVIDED IN SCHEDULE II-H-1.3.

- A. Energy usage at the meter is computed from the AMS and IDR 15-minute interval
  data. For each day, energy is summed across the 96 intervals that contribute to that
  day. Daily data are summed across days to give the calendar month sum.
- Energy usage at the source is computed from the AMS and IDR 15-minute interval data. For each interval, energy use is scaled upward for the distribution and transmission loss factor for that interval. The scaled values are then summed across the 96 intervals that contribute to each day, and the daily values are summed across days. The result is monthly energy by class at the source. The monthly loss multiplier for energy can then be calculated as the ratio of the energy sum with losses to the energy sum without losses.
- 14 Q. PLEASE DESCRIBE THE PROCESS FOR DETERMINING THE
  15 RESULTS FOR CLASS COINCIDENCE FACTORS AND CLASS LOAD
  16 FACTORS PROVIDED IN SCHEDULE II-1.3.
- A. Class coincidence factors are computed directly from the 15-minute AMS data. For
  each class, the class peak in a month is identified as the maximum 15-minute value
  in the month.
- 20Class loads at the time of the ERCOT peak are extracted from the AMS data21for the 15-minute interval in which the ERCOT peak occurs.
- The value reported as the coincidence factor is the ratio of the class load at the time of the ERCOT peak in each month to the class peak in each month. This
value is 100% in months when the class peak occurs exactly at the same interval as
 the ERCOT peak. Otherwise, it is less than 100%.

Class load factors are also computed directly from the AMS data. For each calendar month, AMS energy is computed as the sum of the class load data for 15minute intervals that fall in that month. The class peak in a month is identified as the maximum 15-minute value in the month. The load factor is the ratio of the average hourly energy value in a month to the class peak in that month.

#### 8 X. WEATHER ADJUSTMENTS AND ADJUSTED TEST-YEAR LOAD DATA

9 Q. PLEASE DESCRIBE THE PROCESS FOR DETERMINING THE
10 WEATHER ADJUSTMENTS REPORTED IN SCHEDULE II-H-1.3.1 AND
11 THE WEATHER ADJUSTED ENERGY AND LOAD DATA REPORTED IN
12 SCHEDULE II-H-1.4.

A. Weather adjustments are reported for all classes in Schedule II-H-1.3.1 at the meter and at the source. Adjusted energy and demand values are reported in Schedule II-H-1.4 for all classes. At a high level, the method is the same for all energy and demand concepts. The actual value is calculated from AMS or IDR interval data. The adjustments are computed using statistical models of the daily or monthly data to estimate the impacts of weather deviations from normal. The adjusted values at the meter are computed as the actual value minus the estimated weather impact.

To compute weather adjusted values at the source, the weather adjusted values at the meter are scaled upward for distribution and transmission loss factors. The loss factors applied to the adjusted loads are the same as the loss factors applied to the actual loads.

1Q.PLEASE DESCRIBE THE PROCESS FOR DETERMINING THE2WEATHER ADJUSTMENTS FOR CUSTOMER MAXIMUM DEMAND AT3THE METER AND AT THE SOURCE PROVIDED IN SCHEDULE II-H-41.3.1.

5 A. The calendar month demand models are discussed earlier in the testimony and 6 include variables for the hottest day (maximum CD70) and the coldest days 7 (maximum HD55) in each month. The models are estimated using monthly data 8 for 2018.

9 The estimated models are used to simulate demand values with normal 10 weather inputs. The difference between model predicted values with actual 11 extreme weather and simulated values with normal extreme weather are the weather 12 impacts on demand. The weather adjustment values are the inverse of the impact values, and are reported on Schedule II-H-1.3.1. The impacts are subtracted from 13 14 the actual demand values and the result is further adjusted for customer growth to 15 give adjusted calendar month customer demands as at the meter reported on 16 Schedule II-H-1.4.

For each class, adjusted customer demand at the meter is converted to adjusted customer demand at the source by applying distribution and transmission loss factors computed for monthly energy. These are the same loss factors that are applied to the unadjusted demand data.

## Q. PLEASE DESCRIBE THE PROCESS FOR DETERMINING THE WEATHER ADJUSTMENTS FOR CLASS PEAK DEMAND AT THE METER AND AT THE SOURCE PROVIDED IN SCHEDULE II-H-1.3.1.

A. Weather adjustments to monthly class peaks are computed using the daily class
peak models. Daily class peak models are discussed earlier in the testimony and
include CD spline and HD spline variables that embody the nonlinear relationship
between temperature and daily class peak. These variables appear in the models
directly and also interacting with weekend variables and seasonal variables that
allow the weather response to be different on different types of days.

10 Daily class peak models are estimated with actual daily weather data. The estimated models are used to recalculate what daily class peaks would have been 11 12 with normal weather on each day. For each month, the difference between the 13 maximum predicted class peak with actual weather and the maximum simulated 14 class peak with normal weather is the class peak weather impact for the month. The 15 weather adjustment values are the inverse of the impact values, and are reported on 16 Schedule II-H-1.3.1. The impacts are subtracted from the actual class peaks, and 17 the result is further adjusted for customer growth, giving the adjusted class peak at 18 the meter reported on Schedule II-H-1.4.

19To derive weather adjusted class peak values at the source, distribution and20transmission loss factors for the actual class peak interval in each month are applied21to the weather adjusted value at the meter.

1 **O**. PLEASE DESCRIBE THE PROCESS FOR DETERMINING THE 2 WEATHER ADJUSTMENTS FOR CLASS LOAD AT THE TIME OF 3 **CENTERPOINT HOUSTON PEAK PROVIDED IN SCHEDULE II-H-1.3.1** 4 Α. Weather adjustment to class loads at the time of CenterPoint Houston monthly peak 5 are computed using models of daily class coincident loads. Daily loads at the time 6 of CenterPoint Houston peak are computed directly from the 15-minute AMS data 7 based on the time of the Company's peak on each day. Daily coincident load 8 models are discussed earlier in the testimony and include CD spline and HD spline 9 variables. These variables appear in the models directly and also interacting with 10 weekend variables and seasonal variables that allow the weather response to be 11 different on different type of days. 12 Daily coincident load models are estimated with actual daily weather data.

13 The estimated models are used to recalculate what daily coincident class loads 14 would have been with normal weather on each day. On the Company's peak day 15 in each month, the difference between predicted coincident class load with actual 16 weather and simulated coincident class load with actual weather is the class load 17 weather impact for that month. The weather adjustment values are the inverse of 18 the impact values, and are reported on Schedule II-H-1.3.1. The impacts are 19 subtracted from the actual coincident load values, and the result is further adjusted 20 for customer growth, giving the weather adjusted class coincident load at the meter 21 reported on Schedule II-H-1.4.

1 To derive adjusted values at the source, distribution and transmission loss 2 factors for the interval of the CenterPoint Houston monthly peak are applied to the 3 adjusted value at the meter.

# 4 Q. PLEASE DESCRIBE THE PROCESS FOR DETERMINING THE 5 WEATHER ADJUSTMENTS FOR CLASS LOAD AT THE TIME ERCOT 6 PEAK PROVIDED IN SCHEDULE II-H-1.3.1.

7 Weather adjustment to class loads at the time of ERCOT monthly peak are A. 8 computed using models of the ERCOT coincident loads for each class. Daily loads 9 at the time of ERCOT peak are computed directly from the 15-minute AMS data 10 based on the time of the ERCOT peak on each day. Daily coincident load models 11 are discussed earlier in the testimony and include CD spline and HD spline variables. These variables appear in the models directly and also interacting with 12 13 weekend variables and seasonal variables that allow the weather response to be 14 different on different type of days.

15 Daily coincident load models are estimated with actual daily weather data. 16 The estimated models are used to recalculate what daily coincident class loads 17 would have been with normal weather on each day. On the ERCOT peak day in 18 each month, the difference between predicted class coincident load with actual 19 weather and simulated class coincident load with normal weather is the weather 20 impact for that month. The weather adjustment values are the inverse of the impact 21 values, and are reported on Schedule II-H-1.3.1. The impacts are subtracted from 22 the coincident load value for the month, and the result is further adjusted for

customer growth, giving the adjusted class coincident load at the meter reported on
 Schedule II-H-1.4.

To derive adjusted values at the source, distribution and transmission loss factors for the interval of the ERCOT monthly peak are applied to the adjusted value at the meter.

## 6 Q. PLEASE DESCRIBE THE PROCESS FOR DETERMINING THE 7 WEATHER ADJUSTMENT RESULTS FOR ENERGY USAGE AT THE 8 METER AND AT THE SOURCE PROVIDED IN SCHEDULE II-H-1.3.1

9 A. Weather adjustments to calendar month energy are computed using the daily energy 10 models. Daily energy models are discussed earlier in the testimony and include CD 11 spline and HD spline variables that embody the nonlinear relationship between 12 temperature and daily energy. These variables appear in the models directly and 13 also interacting with weekend variables and seasonal variables that allow the 14 weather response to be different on different types of days.

15 Daily energy models are estimated with actual daily weather data. The 16 estimated models are used to recalculate what daily energy would have been with 17 normal weather on each day. The difference between the predicted daily energy 18 with actual weather and simulated daily energy with normal weather is the weather 19 impact for a day. Daily weather impacts are summed across days in the calendar 20 month. The monthly weather adjustment values are the inverse of the monthly 21 weather impact values, and are reported on Schedule II-H-1.3.1. The monthly 22 weather impacts are subtracted from actual monthly energy values and the result is

1	further adjusted for customer growth, giving the weather adjusted monthly energy
2	at the meter reported on Schedule II-H-1.4.

To derive weather adjusted energy at the source, distribution and transmission loss factors for actual monthly energy in a month are applied to the weather adjusted value at the meter.

Q. PLEASE DESCRIBE THE PROCESS FOR DETERMINING THE
 RESULTS FOR ADJUSTED CLASS COINCIDENCE FACTORS AND
 ADJUSTED CLASS LOAD FACTORS PROVIDED IN SCHEDULE II-H 1.4.

A. Adjusted class coincidence factors are computed from the weather adjusted
 ERCOT coincident load values and the weather adjusted class peak values, both of
 which are discussed above.

Adjusted class load factors are computed from the weather adjusted
calendar month energy values and the weather adjusted monthly class peak values,
both of which are discussed above.

#### 16 17

#### XI. ADJUSTED REVENUE MONTH CUSTOMER DEMAND AND BILLING DEMAND

18 **Q**. PLEASE DESCRIBE THE PROCESS FOR DETERMINING THE 19 WEATHER ADJUSTMENT FOR REVENUE MONTH CUSTOMER 20 **DEMAND (KVA) PROVIDED IN WORKING PAPER EXHIBIT WP H-4.1.** 21 A. Revenue month customer demand is the sum of maximum customer demands for 22 each billing cycle that contributes to the revenue month. The only classes that have 23 demand as a billing determinant are large secondary (SVL) and primary (PVS). As discussed earlier in the testimony, monthly demand data from the middle of 2015 24

through 2018 are used to estimate models that use two-month weighted inputs as
 the explanatory variables. The explanatory variables are monthly class peaks,
 maximum values of HD55 for extreme cold weather, and maximum values of and
 HD70 for extreme warm weather.

5 These models are simulated using weather adjusted class peaks and normal 6 maximum HD55 and HD70 values. For each month, the difference between the 7 predicted value with the actual inputs and the simulated value with the normal 8 inputs is the weather impact. The weather impact for each month is subtracted from 9 the demand value and is further adjusted for customer growth, giving the adjusted 10 revenue month demand value. The unadjusted values, the weather adjustment, and 11 the adjusted monthly values are presented in Schedule WP-H-4.1.

Q. PLEASE DESCRIBE THE PROCESS FOR DETERMINING THE
 WEATHER ADJUSTMENT FOR MONTHLY BILLING DEMAND (KVA)
 PROVIDED IN WORKING PAPER EXHIBIT WP H-4.1.

A. Revenue month billing demands are larger than customer demand values in a month
because of the 80% ratchet calculation. Four weather sensitive classes include
billing demand as a billing determinant (SVL, PVS, SVL\_IDR, and PVS\_IDR). As
discussed earlier in the testimony, monthly demand data from the middle of 2015
through 2018 are used to estimate models.

For SVL and PVS, the billing demand model uses actual revenue month demand as the explanatory variable. This allows weather adjustments for monthly demand to be translated into weather adjustments for billing demand.

1		For SVL_IDR and PVS_IDR, the billing demand model uses the two-month
2		weighted inputs as the explanatory variables, which include monthly class peaks,
3		maximum values of HD55 for extreme cold weather, and maximum values of and
4		HD70 for extreme warm weather.
5		These models are simulated using weather adjusted values and normal
6		weather values. For each month, the difference between the predicted value with
7		the actual inputs and the simulated value with the normal inputs is the weather
8		impact. The weather impact for each month is subtracted from the billing demand
9		value and is further adjusted for customer growth, giving the adjusted billing
10		demand value. The adjusted and unadjusted monthly values, the weather
11		adjustment, and the adjusted monthly values are presented in working paper exhibit
12		WP H-4.1.
13	Q.	PLEASE DESCRIBE THE PROCESS FOR DETERMINING THE
14		WEATHED ADDISTMENT FOD EDCOT CONCIDENT DEMAND
		WEATHER ADJUSTMENT FOR ERCOT COINCIDENT DEMAND
15		(4KVA) PROVIDED IN WORKING PAPER EXHIBIT WP H-4.1.

5		These multipliers are applied to the 4CP demand values reported for all months in
6		2018 as reported on the working paper exhibit WP H-4.1 (Weather Impact).
7		XII. <u>CONCLUSIONS</u>
8	Q.	PLEASE SUMMARIZE YOUR TESTIMONY AND
9		RECOMMENDATIONS.
10	А.	15-minute AMS and IDR interval data provide the opportunity to understand
11		weather adjustments at a deeper level than was possible with monthly billing data.
12		The 15-minute interval data also provide exact values for daily energy, daily class
13		peaks, and daily coincident load calculations.
14		Using these data, it is possible to build daily weather adjustment models
15		that account for the nonlinear relationship between load and weather, and to make
16		adjustments that recognize the difference between low, medium, and high-powered
17		degrees. Also, it is possible to identify seasonal differences in the strength of

18 weather response, allowing Spring and Fall responses to differ from Summer and

1	Winter responses. The result is a set of weather adjustments that are accurate and
2	that are based on powerful statistical relationships. These results provide a strong
3	foundation for revenue requirement calculations based on weather adjusted billing
4	determinants.

## 5 Q. ARE THE ADJUSTMENTS DISCUSSED IN YOUR TESTIMONY 6 REASONABLE AND APPROPRIATE?

7 A. Yes.

#### 8 Q. DOES THIS CONCLUDE YOUR DIRECT TESTIMONY?

9 A. Yes, it does.

#### COUNTY OF SAN DIEGO §

#### AFFIDAVIT OF JOHN STUART MCMENAMIN

BEFORE ME, the undersigned authority, on this day personally appeared John Stuart McMenamin who having been placed under oath by me did depose as follows:

- 1. "My name is John Stuart McMenamin. I am of sound mind and capable of making this affidavit. The facts stated herein are true and correct based upon my personal knowledge.
- 2. I have prepared the foregoing Direct Testimony and the information contained in this document is true and correct to the best of my knowledge."

Further affiant sayeth not.

3/9/2019 John Stuart McMenamin

SUBSCRIBED AND SWORN TO BEFORE ME on this <u>9</u> day of <u>March</u>, 2019.

Notary Public in and for the State of California

My commission expires: Dec. 1, 2019

#### Dr. J. Stuart McMenamin

#### Education

- Ph.D., Economics, University of California, San Diego, 1975
- B.A., Mathematics and Economics, Occidental College, 1971

#### **Employment History**

- Director of Forecasting Solutions, Itron, Inc., 2002-present
- Senior Vice President, Regional Economic Research, Inc., 1986-2002
- Vice President, Criterion Inc., 1979-1985
- Senior Economist, President's Council on Wage and Price Stability, 1978-1979
- Lecturer in Economics, University of California, San Diego, 1976-1989
- Research Director, Econometric Research Associates, 1975-1978
- Senior Consultant, Institute for Policy Analysis, 1973-1975

#### **Research Experience**

Dr. McMenamin is a nationally recognized expert in the field of energy forecasting. Over the last 40 years, he has specialized in the following areas: end-use modeling, energy technology data development, end-use load shape modeling, system load forecasting, price forecasting, retail load forecasting, financial forecasting, load research data analysis, and smart grid data analytics. In addition to his work in the energy area, Dr. McMenamin has completed numerous studies in the areas of telecommunications markets, regional economic modeling, and statistical analysis of employment practices.

Prior to joining Itron, Dr. McMenamin was the principal investigator for the development of the EPRI end-use models (REEPS, COMMEND, and INFORM) which were the primary end-use modeling tools in North America in the 1980s and 1990's. Since joining Itron in 2002, Dr. McMenamin has directed the development of Itron's forecasting software products (MetrixND, MetrixLT, Forecast Manager, and the Itron Load Research System). These products are used by most of the major utilities and ISOs in North America for shortterm forecasting and financial forecasting.

In the area of data development, Dr. McMenamin has directed numerous market research studies involving residential, commercial, and industrial customers. These studies have included large on-site survey projects in all sectors, decision-maker studies, vendor surveys, panel of experts studies, and conjoint studies. Results from these studies have been used to construct comprehensive market assessments involving the modeling of customer purchase actions and customer decision processes.

Over the last decade, Dr. McMenamin has spearheaded the development of the Statistically Adjusted End-Use modeling framework, which has been adopted by a growing list of major utilities for long-term forecasting. More recently, Dr. McMenamin has focused on analysis of smart meter data and applications of these data to forecasting, weather normalization, and variance analysis.

#### **Teaching Experience**

Undergraduate courses taught at the University of California, San Diego (1976-1989).

- Topics in Economics
- Principles of Microeconomics
- Money and Banking
- International Finance

1	EXECUTIVE SUMMARY OF MATTHEW A. TROXLE
2	My testimony addresses four areas: (1) the twelve-month period ending
3	December 31, 2018 Test Year ("Test Year") billing determinants used to design the
4	proposed retail delivery service rates; (2) the allocation of costs among the rate classes;
5	(3) the development of CenterPoint Energy Houston Electric, LLC's ("CenterPoint
6	Houston" or the "Company") proposed retail and wholesale delivery service tariff rate
7	schedules, riders and various charges; and (4) other proposed changes to the Company's
8	retail delivery service tariffs. Specifically, my testimony:
9 10 11	• explains the reasonable and necessary adjustments to the Test Year billing determinants that are necessary to make the Test Year billing and usage data more representative of conditions that are expected to exist once new rates go into effect;
12 13 14 15 16	• describes the two class cost of service studies used to allocate costs among the rate classes in accordance with the Federal Energy Regulatory Commission System of Accounts, the Public Utility Regulatory Act, the Public Utility Commission of Texas' rules and rate filing package instructions, and the principles of cost causation;
17 18 19 20	• explains, for both the retail delivery service tariff and the wholesale delivery service tariff, how each rate schedule applies and how each delivery charge is calculated, and also demonstrates that these rate schedules and riders accurately recover the cost of service as described and supported in the rate filing package;
21 22 23 24	• introduces a new rider, Rider UEDIT – Unprotected Excess Deferred Income Tax, that refunds to customers the balance of unprotected excess deferred income taxes resulting from the Tax Cuts and Jobs Act of 2017 that changed the federal income tax rate in 2018;
25 26 27	• describes the Company's proposed additional charges and discretionary service charges and the methodology used to determine the present cost of providing these services; and
28	• summarizes other proposed changes to the Company's retail tariff.

- 1 The current and proposed base class revenues, inclusive of Rider TCRF, DCRF and UEDIT
- 2 are as follows:

#### CENTERPOINT ENERGY HOUSTON ELECTRIC, LLC SUMMARY OF REVENUES BY RATE CLASS

<sup>1</sup>Test Year revenues have been adjusted to normalize billing units and adjust for DCRF and TCRF

#### **1 DIRECT TESTIMONY OF MATTHEW A. TROXLE**

2

#### I. INTRODUCTION

#### **3 Q. PLEASE STATE YOUR NAME AND CURRENT POSITION.**

4 A. My name is Matthew A. Troxle. I am Director of Regulatory Affairs for
5 CenterPoint Energy Service Company, LLC ("Service Company").

#### 6 Q. WHAT ARE YOUR PRESENT RESPONSIBILITIES?

7 A. As Director of Regulatory Affairs, I am responsible for developing and directing 8 communicating CenterPoint Energy regulatory strategy and Houston 9 Electric, LLC's<sup>1</sup> ("CenterPoint Houston" or the "Company") position on complex 10 business and regulatory issues to various parties. In addition, I oversee regulatory 11 filings with the regulatory commissions in the various states in which the Company 12 does business, along with ensuring that regulatory orders and decisions are 13 accurately implemented.

#### 14 Q. DESCRIBE YOUR EDUCATIONAL BACKGROUND, AS WELL AS YOUR

#### 15 BUSINESS AND PROFESSIONAL EXPERIENCE.

A. I graduated from Louisiana State University in 1995 with a Bachelor of Science
degree in Business Administration Pre-Law. In 1997, I received the degree of
Master of Science in Economics from Louisiana State University. I began my
employment with the Louisiana Public Service Commission in 1997 as an
Economist in the Economics and Rate Analysis Division. In 1999, I began
employment with the Public Utility Commission of Texas ("Commission") as a

<sup>&</sup>lt;sup>1</sup> "CenterPoint Energy Houston Electric, LLC" is the legal name for the electric utility company that includes not only the regulated transmission and distribution utility but also the transition bond subsidiaries established to collect transition bond charges and restoration bond charges.

1	Rate Analyst, in 2000 I was named Senior Rate Analyst, and in 2005, I was named
2	the Director of Retail Market Oversight. In 2007, I was named the Director of
3	Tariff and Rate Analysis. In 2008, I began employment with Service Company as
4	a Manager of Gas Rates in the Regulatory and Government Affairs organization.
5	In 2012, I was named Director of Rates, and in 2015 I assumed the position of
6	Director of Regulatory Affairs.

### 7 Q. HAVE YOU PREVIOUSLY PROVIDED TESTIMONY BEFORE THE 8 COMMISSION?

9 A. Yes. Please see my Exhibit MAT-1 for a list of the Commission proceedings in
10 which I have provided testimony.

#### 11 Q. ON WHOSE BEHALF ARE YOU TESTIFYING?

12 A. I am testifying on behalf of CenterPoint Houston, the Applicant in this case.

#### 13 Q. HAVE YOU PREPARED ANY EXHIBITS?

A. Yes. I sponsor the exhibits shown in my list of exhibits. These exhibits were
prepared by me or under my direction and control. The information contained in
these exhibits is true and correct to the best of my knowledge and belief.

### 17 Q. HOW DOES YOUR TESTIMONY RELATE TO THAT OF OTHER 18 WITNESSES IN THIS PROCEEDING?

A. In general, other Company witnesses sponsor the specific weather adjustments
 made to billing determinant data, costs and revenue requirements that are
 incorporated into the cost allocation model, the rate design model, and the proposed
 tariffs. The direct testimony of Company witness Kenny M. Mercado will present

the list of witnesses in this proceeding that will provide further discussion of the
 topics.

### 3 Q. WHAT IS THE PURPOSE OF YOUR TESTIMONY IN THIS 4 PROCEEDING?

5 The purpose of my testimony is to: (1) sponsor the proposed twelve-month period A. ending December 31, 2018 ("Test Year") billing determinant adjustments made to 6 7 energy sales, demands, and year-end customer count; (2) present CenterPoint 8 Houston's Class Cost of Service Study ("CCOSS") in support of the Company's 9 proposed delivery system charges in its Tariff for Retail Delivery Service ("Retail 10 Tariff") and the Company's proposed wholesale transmission rates in its Tariff for 11 Wholesale Transmission Service ("WTS Tariff"); (3) support the calculation of the 12 proposed delivery system and discretionary service charges in its Retail Tariff, and 13 the proposed wholesale transmission rates in its WTS Tariff; (4) explain the policy 14 reasons for any proposed rate design changes for delivery system charges in the 15 Retail Tariff; and (5) support the proposed non-rate changes to various provisions 16 in Chapters 2 and 6 of the Retail Tariff. In my testimony, the terms "delivery 17 system charges" and "discretionary charges" have the respective meanings given 18 for those terms in Section 1 of the Retail Tariff.

### 19 Q. DO YOU SPONSOR ANY SCHEDULES IN THE RATE FILING 20 PACKAGE?

A. Yes. I sponsor or co-sponsor the following Rate Filing Package ("RFP") schedules
that relate to and support the Company's Test Year Customer Billing Determinant
Data, CCOSS, Class Cost Allocation process, and Rate Design process:

<u>Schedule II-H-1: Summary of Test Year Adjustments</u> – This schedule provides the following summary of Test Year data by rate class: year-end number of customers, total adjusted kWh sales.
<u>Schedule II-H-1.1: Test Year Sales Data</u> – This schedule provides the following Test Year data by rate class: average number of customers, year- end number of customers; Test Year kWh (unadjusted sales), increase or decrease in kWh sales due to adjustments for abnormal weather, increase or decrease in kWh sales due to adjustments for changes in customer composition and/or for changes in the number of customers; increase or decrease in kWh sales due to adjustments other than for the effects of weather and customer (e.g. reclassification of customers), reflecting each adjustment separately; and total adjusted kWh sales for the Test Year.
<u>Schedule II-H-1.2: Monthly Sales Data</u> – This schedule provides the data presented in Schedule II-H-1.1 by month of the Test Year.
<u>Schedule II-H-1.5: Adjustments to Operating Statistics</u> – The schedule provides a narrative explanation for all adjustments made to Test Year operating statistics provided above in Schedule II-H-1.
<u>Schedule II-H-3.1: Customer Information</u> – This schedule provides the monthly Test Year number of customers by rate class.
<u>Schedule II-H-3.2: Customer Adjustments</u> – This schedule presents topics and descriptions of the customer adjustments performed by rate class.
<u>Schedule II-H-3.3: Customer Adjustment Data</u> – The purpose of this schedule is to provide adjustment data not already presented in Schedule II-H-3.1 above. This schedule is not applicable, CenterPoint Houston has provided all the customer adjustment data above in Schedule II-H-3.1.
<u>Schedule II-H-4.1: Revenue Impact Data</u> – Provides the Test Year data on revenue impacts of kWh sales and kW/kVA demand adjustments by rate class. The data columns show: revenue associated with any rate annualization adjustments, showing components separately; revenues associated with kWh customer adjustments, showing components separately; revenues associated with kW customer adjustments, showing components separately; revenues associated with kWh weather adjustments, showing components separately; revenues associated with kWh weather adjustments, showing components separately; revenues associated with kW weather adjustments, showing components separately; revenues associated with kW weather adjustments, showing components separately; revenues associated with kW weather adjustments, showing components separately; revenues associated with each adjustment individually, listing components separately; revenues associated with each adjustment individually, listing components separately.

1 2 3	• <u>Schedule II-H-4.2: Revenue Calculation Methodologies</u> – This schedule provides a description of the methodologies used to calculate the adjustments to revenues.
4 5 6	• <u>Schedule II-I-1: Class Revenue Requirement Analysis</u> – Provides a class revenue requirement analysis for the Test Year and displays the functional revenue requirement allocated to each rate class.
7 8	• <u>Schedule II-I-2 Class Allocation Factors</u> – Provides the allocation factors used in each customer class.
9 10 11	• <u>Schedule II-I-3 Functionalized Cost-of-Service Analysis (Non-ERCOT</u> <u>Members)</u> – Because CenterPoint Houston is a member of ERCOT, this schedule is not applicable.
12 13 14 15	• <u>Schedule IV-J-1 Revenue Summary</u> – This schedule provides a summary of the Test Year revenue requirement. The rows of the table display the Test Year revenue requirement by base rate function and approved riders. The columns display the Test Year revenue requirement by rate class.
16 17 18	• <u>Schedule IV-J-2 Proposed Charges for Discretionary Services and Other</u> <u>Services</u> – Provides the proposed charges for each discretionary and other service charge in the Company's tariffs.
19 20	• <u>Schedule IV-J-3 Rate Class Definition</u> – Catalog of rate classes and definitions.
21 22 23 24 25 26 27 28	• <u>Schedule IV-J-5 Billing Determinants</u> – This schedule imparts the following billing summary for each rate class for each month of the Test Year: Billing Demand, Billing kWh, and Number of Customer Bills. Billing Demand details unadjusted, adjustments, and fully-adjusted total. Billing kWh details unadjusted, adjustments (weather and customer changes, and Energy Efficiency Program) and the total fully-adjusted kWh totals. Number of Customer Bills unadjusted, customer growth adjustment, fully-adjusted total.
29 30	• <u>Schedule IV-J-6 Justification for Consumption Level-Based Rates</u> – This schedule is not applicable.
31 32 33 34 35	• <u>Schedule IV-J-7 Proof of Revenue Statement</u> – This schedule provides a proof of revenue statement, presents the class cost of service, the billing units, proposed rates, and the resulting base revenue for the existing and proposed rate classes, and any other Commission-approved non-bypassable charges under both current and proposed rates.
36 37	• <u>Schedule IV-J-8 Rate Design Analysis Data</u> – Provides estimated billing determinants, without ratchet provisions, for peak and off-peak periods as
